ABSTRACT OF

Presidential Address

ON

SOME LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL EXPERIENCES.

Delivered before the British Laryngological, Rhinological, and Otological Association on March 11th, 1904,

BY JOHN BARK, F.R.C.S. EDIN.,
HONORARY SURGEON, THROAT AND EAR DEPARTMENT, STANLEY HOSPITAL, LIVERPOOL, ETC.

[AFTER a few introductory remarks Mr. Bark referred to ie fact that his early professional experience had been ained in general practice and that he had also spent much me as surgeon to a general hospital, which double experience had been of great use to him in his special work. He ontinued :—]

In those days, at any rate in the provinces, our specialty ad no existence, and all that was done for the diseases which re now treat was done by the general surgeon or physician, xcept perhaps "aural surgery," and that chiefly consisted n syringing the ears, twisting out polypi, the occasional use f the Politzer or Eustachian catheter, or in the making of Wilde's incision and was done by the ophthalmologists. True, the laryngoscope was well enough known but scarcely ny but a few advanced physicians used it. I well remember ow in my young days it was quite customary to prepare the atient for several days with good big doses of bromide for laryngoscopic examination. The eye, of course, was ommonly enough looked into but, strange to say, no one oked into the nose. It was strongly instilled into me that e best way to examine the nose was to make a digital xamination with the little finger. I have thought, having o scientific discoveries or special work to bring forward as e subject of this address, that I could not do better than place before you some of the experiences through which I ave passed and the conclusions which I have come to in y 20 years of work. I cannot, of course, deal with verything but I trust that the following *résumé* will not be ut of place.

[Mr. Bark then referred to the enormous advances which ad been made in the treatment of diseases of the nose and roat through the introduction of cocaine. The solution sed must be fresh and in strength from 5 to 20 per cent. or the removal of most nasal polypi he preferred the cold ire snare, but in the case of a large polypus filling the osterior choana or the naso-pharynx he used forceps guided y the finger. In turbinectomy or operations on the septum evere hæmorrhage sometimes occurred. This should be hecked by plugging and the adrenalin solution was also seful at the time of operation. Deviations of the septum ere best treated by Asch's operation or its modifications. or ethmoidal suppuration he punched away the ethmoidal ells with Hartmann's conchotome and had had good results. r. Bark continued :—]

In frontal sinus suppuration I first remove the anterior end the middle turbinal in the hope, which is frequently alised, that this may free the fronto-nasal passage and ecure efficient drainage of the sinus. When this is not ccessful I trephine the sinus and, after removing any ostructions, make a large opening through the floor into the ose, clean out with hydrogen peroxide, plug with antiseptic auze, bringing the end out through the nose, and then ose the external incision. The packing is removed through e nose on the second day. I desire here to express my reat indebtedness to Mr. Mayo Collier from whose work the "Surgery of the Frontal Sinus" we have learnt so uch.

More exact clinical observation and improved methods of xamination have brought many more cases of antral disease nder our notice than was formerly the case. The so called "latent" empyema can scarcely be any longer regarded as tent, its symptoms being so well understood and the xamination of the antrum being so easily made. Still, just s one is never absolutely sure that there is pus in a chest ntil one has explored it with a needle, so it is essential efore operating for maxillary sinus suppuration to intro a trocar. I use a Lichtwitz trocar and perforate the inner wall through the inferior *meatus*. To drain I always operate through the canine fossa in the following way. I use a specially shaped shouldered trocar chisel and, under nitrous oxide anæsthesia, drive it with a single blow of the hammer into the antrum and at once introduce a specially shaped rubber drainage tube made for me by Messrs. Down Bros. This is fitted with a flanged end at an angle of 45°, which lies easily between the gums and cheek and keeps the tube in position. The patient is instructed to wash out the antrum by forcing lotion, by orbiculo-buccinator action, through the tube and antrum into the nose. I find in the majority of cases that this is satisfactory; if not, I do a radical operation on the lines of Caldwell-Spicer.

Laryngologists, I think, do not excise the uvula very frequently, recognising that most of the symptoms that used to be ascribed to its elongation are really due to other causes. It is still, however, very frequently removed by some practitioners who, whenever a patient complains of any subjective throat symptoms or voice fatigue, snip it off with as little compunction as pathological knowledge. We have improved very little in this matter upon the knowledge and practice of even the most ancient surgeons; for example, in the seventh century of our era Paulus Ægineta wrote that it should only be removed when it causes cough, sleeplessness, and suffocation, and then only as much should be removed as exceeds its natural length, as complete extirpation is injurious, he says, to the voice and chest. It is interesting to note that, even then, the uvula was held by a special forceps adapted to the purpose. Speaking of the ancient surgeons and their ways I have been much struck by the method which they employed for excision of the tonsils. Paulus Ægineta operated in the same manner as was still in vogue when I was a student—namely, pulling out the tonsil with a pair of forceps or tenaculum and cutting it off with a knife, called an ancyclotomus. Celsus directs us to "scrape the membrane with the finger and tear it out," which is practically enucleation. Albucasis recommends scissors but also seems to have invented a sort of guillotine and figures an instrument consisting of a lunated piece of iron fixed to a handle. Of the several methods practised at the present time, all of which I at one time or another have tried, I now practically use but two, viz., the guillotine [illegible]

[illegible] operating under nitrous oxide—one has more control of the instrument, and can, therefore, remove the tonsils more completely and expeditiously. Above 15 years of age I now always use the method of morcellement, considering it more [illegible] the whole organ. I use Ruault's punch for the larger portions and finish off with Hartmann's conchotomes. The complete removal of both tonsils can be easily done in this way in one sitting and under cocaine anæsthesia. I have used this method in more than [illegible]00 cases and the hæmorrhage has always been trivial. Hæmorrhage after tonsillectomy is undoubtedly a rare occurrence. In children it is exceedingly rare. Out of 6000 operations on children under 15 years of age I have met with it but twice—in a boy 13 years of age and in a girl [illegible] years of age. The hæmorrhage was severe in both but not alarming in either. I have also met with severe hæmorrhage in five adult cases. In all seven cases the guillotine was used and the anterior pillar of the fauces was not wounded in any and astringent sprays or gargles were useless. In five the hæmorrhage was controlled by steady and continuous pressure by means of a pad soaked in turpentine and adrenalin held on the stump with the middle finger—the thumb of the same hand pressing below the angle of the jaw.

No. 4205.

I have invariably used nitrous oxide and oxygen which I find gives plenty of time for the double operation. When I started operating under gas there was no gag suitable for the purpose. The surgical gags interfered with the administration of the gas and the dental mouth props interfered with the operation. Dr. V. H. W. Wingrave and I brought out, separately, gags which rendered the operation not only possible but easy under the short nitrous oxide anæsthesia. There are a few, but very few, cases for which neither Wingrave's gag nor mine is suitable. When the central incisors project considerably beyond the lateral the gag is apt to slip and in this case I use Doyen's gag, but find it much less comfortable and convenient for general use. I strongly believe in operating with the head hanging over the end of the table. No doubt, to commence with, the operator finds the tongue somewhat in the way for the tonsillectomy, but this difficulty is with very little practice easily surmounted and the advantage of keeping the larynx free from blood alone more than compensates for this. Besides, as regards the adenoids, this position is incomparably superior for using the Gottstein curette and the finger.

The lingual tonsil in my student days was never recognised as a distinct entity. We were certainly aware of the presence of a good deal of adenoid tissue at the root of the tongue, but no one ever thought of attributing any symptoms to it or of treating it surgically. Of course, the common use of the laryngoscope accounts for its perhaps undue prominence during late years. Hypertrophy of this structure is not, in my experience, very common—that is to say, hypertrophy sufficient to produce symptoms. When it occurs it is usually in adults and has given rise to two prominent symptoms—viz., a feeling of fulness at the root of the tongue and occasional sensations of choking. As a rule, galvano-puncture reduces it sufficiently to give relief, but cases sometimes present themselves calling for more radical treatment. I then remove it with a pair of rectangular punch forceps made for me for that purpose about ten years ago by Messrs. Mayer and Meltzer. I have recently met with a case of exceptional enlargement, occurring in a man 54 years of age and consisting of two lobes, each of the size of a Barcelona nut. I have only met with one case of acute abscess of the lingual tonsil. A man, aged 30 years, complained of painful swallowing and the laryngoscope showed a large red swelling of the lingual tonsil, which fluctuated on palpation and which on incision yielded pus with complete relief.

Until the patient and successful work of Krause of Berlin and of Heryng of Warsaw showed us the value of the proper surgical treatment of laryngeal tuberculosis patients were practically left to their fate, local application of morphine, cocaine, and other anæsthetics being the only treatment adopted, and that only in the attempt to relieve the terrible odynphagia. The precepts and example of these two great workers in our specialty have done more for suffering humanity in the alleviation of this terrible symptom than words can describe and although *most sufferers* from laryngeal phthisis inevitably succumb, yet the relief from pain and the consequent ability to take food prolong life and make it more endurable. A few brilliant cases have been reported where even a cure resulted with restoration of voice. I have found both Krause's double curettes and Heryng's curettes of great service in removing the tuberculous infiltration and so facilitating the application of the lactic acid. Another plan of treatment which I have adopted for a few years, especially where the disease has progressed to ulceration, or where owing to the intractability of the patient the above surgical treatment is impossible, is the insufflation of equal parts of orthoform and resorcin. It is *often* quite astonishing how quickly this relieves the symptoms and cleans up the ulcerating surfaces.

In no branch of our art has there been more improvement than in the technique and instruments for use in endo-laryngeal surgery. Formerly, benign growths, foreign bodies, &c, in the upper respiratory passages were removed by means *of* external operations, but now, thanks to the laryngoscope and the various and ingenious instruments which *have been devised*, the practised laryngologist removes such growths as *papillomata*, fibromata, cysts, &c., of the larynx with comparative ease, and even in cases of suspected malignancy a small scrap removed in this way may give positive microscopic evidence and c nt submit to the radical operation m otherwise would have done, which or non-success in these cases.

I have found Dr. J. Dundas Grant's laryngeal forceps o especial value in removing growths from the edges of th cords and have often removed at the first attempt with thes forceps growths that I have failed to remove with others Valuable as this method is in the *treatment* of benign growths, I think all modern laryngologists are agreed tha the complete removal of even the smallest malignant growth in this way is impossible and any attempt to do so I conside unjustifiable and unfair to the *patient*. The successfu removal of a malignant neoplasm necessitates the remova of so much *surrounding tissue and the condition is* so serious that if any operation is to be done it must be an external one, and endolaryngeal *interference*, I think, only increases the rapidity of growth. In my experience, when the growth has affected the parts outside the larynx, any curative operation is out of the question, but when the disease appears to be intrinsic I advise an exploratory thyrotomy, and, should it then be found that the *whole* of the disease can be safely removed, we *may* proceed as far as removing half of the larynx with satisfactory results, but should it be found that the disease is so extensive that complete laryngectomy would be necessary I think it better to proceed no further but to close up the *wound*, as the results of the complete operation are in my experience always unsatisfactory, and I believe that the patients as a rule will live longer and in greater comfort after a *palliative* tracheotomy. The importance of early diagnosis and treatment cannot be over-estimated in cases of malignant laryngeal disease. In all cases of even slight hoarseness lasting over a month a careful examination by a skilled laryngologist is imperative. If this were to become a routine practice thyrotomy would be frequently successful and complete laryngectomy rarely necessary.

Concerning tracheotomy there is really very little to be said and all surgeons are much in agreement on the subject. Intubation, except in the case of syphilitic and other forms of laryngeal stenosis, where it is very valuable and may result in a complete cure, cannot be said to be a substitute for it—certainly not, to my mind, in laryngeal diphtheria. Here I regard tracheotomy, if not done too late, as the best way of averting death from asphyxia and, combined with the use of antitoxin, has in my hands been very successful. Where the membrane extends below the larynx one should not be in a hurry to insert a tube but endeavour to clear out any loose membrane, and I have on several occasions, with success, thoroughly curetted the inside of the trachea, as in two cases reported by my late house surgeon, Mr. J. Lawson Dick, in THE LANCET of July 25th, 1896, p. 242.

The treatment of aural diseases has advanced greatly *in* my time and especially in the case of suppurative *diseases* of the middle ear. From Wilde's incision and perforation of the antrum we have passed to the complete and excellent operation of Stacke which, if the post-aural incision is closed and drainage is maintained through the enlarged external meatus, gives a result so satisfactory and sightly that patients allow it to be done much more frequently and earlier than formerly and risk of serious diseases of the brain and of surrounding parts is minimised. I consider the Schwartze-Stacke operation to be one of the greatest triumphs of modern surgery. There is another operation which is often efficient in relieving middle ear suppuration and is especially valuable in attic suppuration; I refer to ossiculectomy, first suggested by Schwartze in 1873. Performed *with* Delstanche's extracteur de marteau the operation is much easier and is often successful, rendering more serious proceedings unnecessary. This operation has also been much praised in middle-ear sclerosis, but, although I have done *it* a dozen times at least, I have seen no good permanent results.

Gentlemen, I have finished what I fear is but a cursory and imperfect account of some of the views and conclusions *I* have come to in my many years of practice of the branch of medicine we especially study. I trust that I have not overwearied you and in concluding let me express the hope that I have in reviewing the subject made myself clear, that I have given offence to no one, and acknowledged my indebtedness justly to each of those who have helped to construct our little chapel in the great temple of knowledge. As *time* goes on I shall likely enough modify many of my views; our knowledge will extend, new discoveries will be made, and fresh builders will appear on the scene. One portion of our edifice will be pulled down and replaced by other, let us hope always better, work. Another part will from time time require reconstruction and possibly some great event [illegible] pulling down the whole fabric perhaps by two or three [illegible] not that, as necessity arises, our association architects to lan and to devise, and workmen to how and to build, and rom time to time it will be well if someone abler than I vill take a survey of the whole work from his view-point nd indicate what he considers good and what he thinks nferior work. Such I have tried to do to-day and I trust hat my effort has been not altogether unacceptable.

Hunterian Lectures

ON

THE PATHOLOGY AND SURGERY OF CERTAIN DISEASES OF THE PANCREAS.

Delivered before the Royal College of Surgeons of England on March 7th, 9th, and 11th, 1904,

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND

LECTURE III.[1]

Delivered on March 11th.

PANCREATIC CYSTS.

MR. PRESIDENT AND GENTLEMEN,—I have nothing to add to the description, relations, and classification given in Diseases of the Pancreas (Saunders and Co., 1903,) where the subject is fully dealt with and may be studied at leisure.

The surgery of cystic disease of the pancreas is much in advance of pancreatic surgery as a whole and it is a subject in which all authorities are agreed as to the wisdom of simple drainage, which is usually sufficient to bring about relief or cure. In these cases surgery offers a poor opportunity for pathological investigation; for when a pancreatic cyst is found experience has shown that the patient's interest is best considered by a limitation of the incision to a size sufficient to empty and to drain it and not sufficiently large to satisfy pathological requirements. Hence it is highly probable that many reported cases of operations for pancreatic cysts have been for cysts of other origin, and it is an undoubted fact that quite a number of cysts originating from the neighbourhood of the pancreas are only pseudo-cysts, as in two under my own care, where in one a collection of blood and serum filled the lesser peritoneal sac as a result of injury and in another a pseudo-cyst formed rapidly around a necrotic pancreatitis and from the cavity a slough of the pancreas was removed.

The symptoms produced by a pancreatic cyst vary according to the size and seat of the tumour. They are at first dependent on the disease leading to the cystic formation and later to the pressure exercised by the tumour on neighbouring viscera, so that we find digestive disturbance with loss of flesh and epigastric uneasiness or some pain quite early, these being followed in certain cases by very intense pain occurring in paroxysms, by vomiting, constipation, jaundice, and wasting, and later by the presence of a tumour. Fatty stools, azotorrhœa, bulky pale mo [illegible] will be present or absent according [illegible] present in the gland. In [illegible] recently there has been a well-marked pancreatic reaction in the urine, indicating catarrh of the pancreatic ducts or interstitial inflammation, and if this test holds good for cystic disease of the pancreas generally, as I believe it *does*, it will, I think, form an important diagnostic sign in any case of tumour suspected to be pancreatic. In this connexion it may be well to remark that the most frequent cause of cyst development is chronic interstitial pancreatitis in which compression and constriction of the ducts result from a new formation of connective tissue with consequent stagnation of secretion. The Roentgen rays may also form a useful help in diagnosis in certain cases as they will establish the presence or absence of pancreatic calculi which are quite opaque to the x rays.

It is to be borne in mind that there have been cases of pancreatic cyst presenting very few symptoms except the presence of a tumour which have been under observation for a long time and have needed no active treatment, but these cases are exceptional. In my first lecture I referred to the importance of the peritoneal reflections from the pancreas on to the viscera and how they influenced the ultimate position and relations of pancreatic cysts. For instance, a tumour springing from the anterior surface of the head or body of the pancreas above the transverse mesocolon will project into the omental bursa and if small will bulge the stomach forward, or if large will either reach the surface above the stomach, between it and the liver, or pressing forward below the stomach it will bulge between it and the transverse mesocolon. On the state of the fulness of the stomach will depend the extent of contact of the tumour with the abdominal wall. If a cystic tumour arise from the pancreas to the right of the omental bursal reflection, it may make its way forwards to the right hypochondrium and simulate a gall-bladder or right renal or suprarenal cyst. Should a cyst arise from the posterior part of the head or tail of the gland it may project either into the right or left lumbar region and resemble a cyst of the kidney. If a tumour springs from the head of the pancreas below the reflection of the transverse mesocolon but to the right of the mesenteric vessels, it will reach the surface below the hepatic flexure of the colon on the right side and may simulate a right renal tumour or a tumour of the cæcum or ascending colon, as the mesentery will prevent it passing to the left of the spine; but should it arise from the small portion of the processus uncinatus on the left of the mesenteric vessels, but below the attachment of the transverse mesocolon, it may burrow between the layers of the mesentery and simulate a mesenteric cyst, or it may bulge on the left of the mesentery and reach the surface below the transverse colon on the left of the spine, when it may resemble a left renal or ovarian cyst or a tumour of the descending colon or small intestine.

Tumours springing from the pancreas on the left of the duodeno-jejunal junction, where the lower surface of the gland lies on the transverse mesocolon, have a tendency to press the great omentum forward and to project above the transverse colon, but they may grow downward toward the central region of the abdomen and arch the transverse colon or even project below it so that the colon lies above the tumour. In an interesting case recently recorded by Dr. S. P. Phillips a thin-walled pancreatic cyst springing from the head of the pancreas completely filled the abdomen and presented the physical signs of ascites. Although usually unilocular, pancreatic cysts may be multilocular as in two of the specimens on the table, photographs of which I will show on the screen. I will now show on the screen several photographs to illustrate the anatomical relations of various pancreatic cysts that I have seen and the surface dulness on percussion that may be expected; they have been recorded from the 12 cases on which I have operated.

TREATMENT.

Occasionally excision of the cyst may be performed, as in a case under my own care in a woman, aged 38 years, where the tumour returned after drainage and where the patient made a complete recovery after the second operation; but the greater difficulty in performing excision, the impracticability of doing it always, and the greater mortality attending it as compared with the old operation of incision and drainage, render it quite clear that the lesser operation should always be tried first unless the circumstances be very exceptional. Aspiration and other forms of tapping are antiquated and ineffective methods which are attended with more danger than the operation of incision and drainage and therefore not to be recommended even for diagnostic purposes; this also applies, though in a lesser degree, to operation *à deux temps* which is now rarely performed. As to the situation for drainage, that must entirely depend on circumstances; the cyst will usually be attacked from the front, where it is manifestly nearest the surface. Occasionally it may be drained from the loin as in a case under my own care. Fistula does not as a rule follow the drainage of pancreatic cysts, but in some cases a small fistula may persist and I have known a fistula to go on for years without hurt to the patient and with very little discomfort. In the cases I have operated on a cyst was enucleated on one occasion, recovery following; drainage was carried out in nine other cases of true cyst and was followed by recovery in eight, whereas of two pseudo-cysts, one due to traumatic hæmorrhagic pancreatitis and the other to necrotic pancreatitis, one recovered. These I shall hope to report more fully before one of the London societies, as the time will not permit me to dwell longer on them now.

---

[1] Lectures I. and II. were published in THE LANCET of March 19th (p. 773) and 26th (p. 845), 1904, respectively.

An extensive search through literature, in which I have been assisted by Mr. A. Clarke of the Royal Medical and Chirurgical Society's Library, who has verified the references for me, reveals the following facts. 160 cases of operation have been recorded; in 140 recovery took place or is presumed to have taken place; in four cases the ultimate issue was doubtful; in eight out of the 140 of reported recovery after operation the patients died subsequently—one from diabetes four months later, one from tuberculosis three months later, one from hæmorrhage one and a half years later, one from concomitant peritonitis seven weeks later, one from a zymotic fever a few weeks later, and three from causes not stated a few weeks later. Death is recorded as the result of operation in 20 cases. In five of these the cause and time after operation are not given. One patient died in collapse, one died before operation could be completed (the next day), one died from "ileus," one died 18 days after operation (cause not stated), two died from shock, one died from gangrene of the pancreas, and eight died from peritonitis. Of these eight dying from peritonitis, one died at interval not stated, one after 96 hours, one after six days, one after an exploratory incision, two after two days, one on the eighth day, and one on the second day. In 138, incision and drainage were performed with 16 deaths, equal to a mortality of 11·6 per cent. In 15 excision was performed, with three deaths, equal to a mortality of 20 per cent. In seven partial excision was done with one death, equal to a mortality of 14 3 per cent. Although larger numbers have been reported by others, the above figures are as nearly correct as appears to be possible, for on verifying the records sometimes the same case had been reported twice, in others wrong dates had been given, and in a few the details were so meagre that the nature of the operation was not given. The evidence is clearly in favour of drainage but the mortality should certainly be reduced by one-half. As to the frequency of cysts of the pancreas Dr. W. Hale White has recorded that in nearly 6000 post-mortem examinations at Guy's Hospital, 1883 to 1894, pancreatic cysts were only found in four cases and one of these was a hydatid cyst.

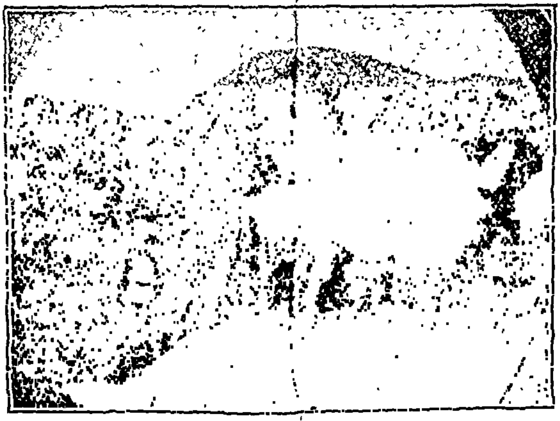
INJURIES OF THE PANCREAS.

Injuries of the pancreas have been so recently and so ably dealt with by von Mikulicz Radecki[2] that I need not spend much time on the subject. It is quite clear that injury to the pancreas is not necessarily fatal, as shown by the development of cysts the result of accident and their successful treatment. The indications for operation depend on the severity of the symptoms and on the presence of either hæmorrhage or inflammation, which may demand operation. If, therefore, after an injury in the superior abdominal region there be increasing anæmia, the signs of free blood in the peritoneum, or peritonitis, the surgeon will be called on to operate without delay. Severe injuries of the pancreas not operated on terminate fatally in nearly every case. Out of 45 cases of pancreatic injury collected by von Mikulicz 24 were perforating, 12 were gunshot, and nine were stab wounds. Of the gunshot injuries five were operated on, three recovering; the seven not operated on all died. Of the stab wounds all were operated on and eight out of nine recovered. Of the 24 subcutaneous injuries 13 were not operated on and all died. Of the 11 operated on seven recovered. No hard-and-fast rule can be formulated as to the method of treatment; the injured part must be exposed and either ligature of vessels or suture of surfaces adopted, but gauze tampons and drainage form important features in any of these operations, and where the peritoneum has been generally soiled with blood and pancreatic effusion lavage with hot saline fluid affords the double advantage of relieving shock and cleansing the abdomen. In view of the favourable results obtained by operation and the lethal effects of non-operative treatment, the only lesson that can be drawn is that we should make an exploratory laparotomy whenever there is a question of severe pancreatic injury. The photograph now thrown on the screen illustrates an extensive hæmorrhage in and around the pancreas the result of injury; it is from a specimen at St. Bartholomew's Hospital Museum, kindly lent for this lecture.

PANCREATIC CALCULUS.

Although two cases of pancreatic calculi were observed by Panarol and Gaiea in 1667 and by others at later dates they are so uncommon that Oser quite recently said there were only 70 recorded cases. I have heard of seven since not included in that series but doubtless there are many unrecorded. The subject of pancreatic concretions can never assume the importance that attaches to cholelithiasis, but as they are associated with serious and usually progressive disease of the gland, and as they can be removed by operation, their recognition and treatment is a matter that demands some consideration. I believe that calculi never form in a healthy pancreas and it seems highly probable that, like gall-stones, pancreatic concretions are the result of catarrh of the ducts with stagnation of secretion, which generally if not always results from infection. Instead of calculi being formed the ducts may actually be lined with calcareous material that may accumulate so much as to close completely, or almost completely, the lumen. An example of this (for which I am indebted to the University College Hospital Museum) I will show on the screen. It will be noticed that the duct of Wirsung is widely dilated and that it also contains calculi. A convenient term for this disease may be "pancreolithic catarrh." As a rule the calculi are numerous and in only three known cases has a solitary calculus been found. The photographs I now throw on the screen showing numerous calculi are from the Royal College of Surgeons of England and the Leeds Museum, to the pathological curators of which I am deeply indebted (Fig. 13). They all show multiple calculi and in every case it will be seen how seriously the glands have deteriorated. In every case they are the seat of cysts, dilated ducts, chronic interstitial pancreatitis, or abscess along with the concretions.

FIG. 13.



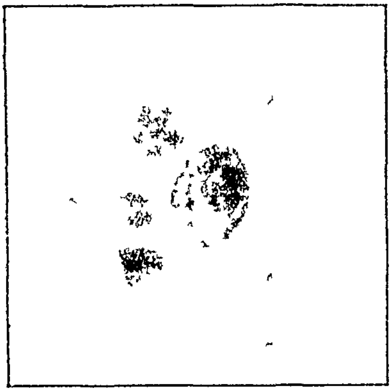
Pancreas containing calculi (Leeds Museum).

The composition of pancreatic calculi is important from the diagnostic point of view, for they contain lime either in the form of carbonate or phosphate or, as in one case reported by Mr Shattock, of oxalate, which latter was found in a cyst. In examining the urine of cases suffering from chronic pancreatitis oxalate of lime crystals have been found by Dr. Cammidge in over 40 per cent. In jaundiced cases in which the bile acids take up the lime salts they have been found only in 6 per cent. of cases. It would be interesting to know if this fact has any bearing on the composition of pancreatic concretions, for it is a well-known fact that the normal pancreatic secretion contains no calcium carbonate. The subject is worthy of further investigation. The consequence of this chemical composition is that pancreatic calculi are opaque to the x rays and in this way we have a means of diagnosing their presence and of differentiating them from gall-stones, which are not seen in a skiagram. I am able to show you on the screen an x ray photograph of concretions taken from a case where at the same time I removed gall stones and pancreatic calculi, and for comparison I show an ordinary photograph of the two classes of concretions together The difference in their appearance in the skiagram is readily seen (Fig 14) The next photograph, taken by Dr J Mackenzie Davidson, shows the calculi *in situ* and as the vessels have been injected they also show distinctly So far as I know this method of diagnosis is here suggested for the first time I feel confident that in future it will be employed regularly and I believe that by means of the urinary pancreatic reaction we shall also be able to confirm the diagnosis by demonstrating the associated chronic pancreatitis

---

[2] Annals of Surgery.

FIG 14



X ray photograph of biliary and pancreatic calculi

I will now show on the screen a number of calculi showing their usual elongated shape Shupmann has recorded a calculus measuring two and a half inches by half an inch and weighing 200 grains, and Matani has reported one weighing two ounces In colour they are pale and they may be white, but if they pass into the common bile-duct they receive a covering of cholesterine and may be stained by the bile so as to look like gall stones The symptoms depend on the associated condition, whether that be cyst, abscess, chronic inflammation, or other pathological state, doubtless in some cases symptoms are vague or even wanting and in some cases pancreatic calculi have only been discovered post mortem Glycosuria was recorded by Lancereux in 12 out of 40 cases Pains at the epigastrium radiating towards the inferior angle of the left scapula, often agonising in character and associated with vomiting, may be present and the attacks may be brought on by exertion or may be irregular, coming on at any hour, day or night Dyspepsia and flatulence are usually associated Liporrhœa and azotorrhœa as well as bulky pale motions, are present when there is well marked interstitial pancreatitis, and in some cases where the interstitial changes have advanced to atrophy or fatty degeneration of the whole gland glycosuria is found The pancreatic reaction in the urine was well marked in a case on which I operated and I think it will be generally found If a calculus descends into the ampulla of Vater jaundice will ensue and the case will probably be diagnosed as one of gall stones in the common duct but the urinary pancreatic reaction and the use of the x rays should enable a differential diagnosis to be made.

MEDICAL TREATMENT

The treatment by sialagogues such as injections of pilocarpine, it seems to me, must be useless and mere waste of time Relief to pain may be given by sedatives and other treatment must be adopted as occasion arises but as soon as pancreatic stones can be diagnosed they should be removed, as destruction of the pancreas is otherwise certain and it is quite clear that medical treatment can do no real good in these cases.

SURGICAL TREATMENT

Surgical treatment has until quite recently been merely palliative, but fortunately surgery can now offer a reasonable hope of cure Some years ago I pointed out that the pancreatic duct could be readily explored by an incision in the second part of the duodenum and by then laying open the biliary papilla, when the opening of Wirsung's duct can be seen In this way I have passed a probe two inches along the duct of Wirsung to explore it and have removed a pancreatic calculus from the duodenal end of the duct. A very exhaustive search through English and foreign literature, in which Mr Clarke has helped me, has only resulted in the discovery of five operations for pancreatic calculi Mr A. Pearce Gould's case, operated on March 3rd, 1896 died on the twelfth day from exhaustion In Dr Dalziel's case a stone of the size of a very large pea was removed from the pancreatic duct through an incision in the duodenum, the opening in the duct being stitched to the wound in the posterior wall of the duodenum. As the bile duct was clear there was no jaundice A good recovery followed In Mr B G A Moynihan's case reported in THE LANCET of August 9th, 1902 p 355, a pancreatic stone was removed from the ampulla of Vater through an incision in the duodenum and the patient recovered In Dr L W Allen's case reported in the "Annals of Surgery," 1903, p 741, two calculi were removed from a cyst between the lesser curvature of the stomach and the liver The patient died on the fifth day after operation In a case under my own care, which has not been yet fully reported, I operated on Feb 13th 1903 on a woman aged 57 years, and removed four calculi, one from the duct of Santorini or one of its branches by direct incision into the pancreas close to the common duct, afterwards closing the opening by deep and by peritoneal sutures, the second and third stones I reached through an incision in the duodenum by laying open the papilla, when by means of fine forceps I removed a calculus out of Wirsung's duct, along which I afterwards passed a probe for two inches, and a fourth concretion I removed by direct pancreatotomy from the middle of the duct of Wirsung, the stone being reached by dividing the gastro hepatic omentum drawing the stomach downwards incising the pancreas freely and opening the duct directly on to the stone which was of the size of a small bean and which I show on the screen The duct was then closed with catgut, the wound in the body of the pancreas being sutured so as to leave no dead space and the peritoneal wounds being closed without direct drainage The right kidney pouch was then drained as some infected bile had escaped Recovery was ultimately complete In this case pain and vomiting were marked features and the pancreatic reaction was of the utmost importance from the point of view of diagnosis This is, I believe, the first case in which either the duct of Wirsung or the duct of Santorini has been deliberately opened and, after the removal of a calculus, closed by a suture

THE OPERATION OF PANCREOLITHOTOMY

For the purpose of removing calculi from the pancreas an incision one or one and a half inches to the right of the middle line will be found the most convenient as the fibres of the right rectus can be split and the incision lengthened upwards and downwards without unnecessarily weakening the abdominal wall A sand bag under the lumbar spine will bring the gland several inches nearer the surface If the opening of the duct of Wirsung has to be explored, the second part of the duodenum may be incised and the papilla common to the bile and pancreatic ducts laid open when the edges of the opened diverticulum of Vater can be seized with small catch forceps and drawn to the surface, a probe or fine forceps can then be readily passed into Wirsung's duct and any concretion removed If the calculi are more deeply placed in the ducts the pancreas may be exposed either through the gastro-hepatic omentum by drawing the stomach downwards or by lifting the stomach it may be reached through a slit in the omentum The calculi may be then cut down on and extracted by a scoop or forceps Any bleeding must be arrested by ligatures The duct can be sutured and the incision in the gland must be brought together by buried sutures the peritoneal covering being coapted by a continuous suture If leakage is feared a gauze drain may be applied but the position may be difficult for this and if it has to be done the gauze must be surrounded by a rubber drainage tube and brought through it to the surface. In my case of pancreo-lithotomy I felt the closure of the gland was so secure as not to require gauze packing and the result justified my not using it. When the duodenum is opened it must be closed in the usual way by a muco-muscular and a serous suture, the latter being of fine celluloid thread. The incised papilla need not be sutured. If a calculus be felt in the head of the gland but not in the duct of Wirsung it may be reached by incising the peritoneum over the duodenum and separating it gently from the head of the pancreas, or if more deeply placed near the back of the gland the reflection of peritoneum from the duodenum to the abdominal wall may be incised and the duodenum may then be displaced inwards, when the back of the pancreas will be exposed and if thought advisable it may be incised and treated as in the incision from the front.

NEOPLASMS.

It is quite impossible in a short course of lectures even to touch on all the diseases of the pancreas. I must therefore under this heading confine myself simply to cancer and sarcoma, leaving for another occasion the study of adenoma, lymphoma, and the granulomata, tubercle, and syphilis.

Carcinoma.—Carcinoma is the most common of the neoplasms found in the pancreas. Out of 53,000 necropsies gathered from various sources where post-mortem examinations were presumably carefully made there were 226 cases of primary malignant disease of the pancreas (Roswell Park), but as these include Remo Segré's cases from the Ospedale Maggiore, Milan, in which the primary and secondary growths are not separated, the proportion of primary growths is probably not so large. Secondary growths are much more common, for instance, in Eppinger's statistics, of 1314 necropsies there were 308 cancers in various organs, of which 19 were in the pancreas, but of these only two were primary. It seems advisable to remark here that all past post-mortem records with regard to cancer of the pancreas must be fallacious as until recently cases of chronic interstitial pancreatitis causing occlusion of the common bile-duct were not differentiated. The tumour in cancer may take the form of scirrhus or encephaloid cancer, columnar epithelioma or colloid cancer, and these are given in their order of frequency. I will throw on the screen examples of each of these forms, as well as examples of cancer of the liver secondary to cancer of the pancreas, showing how the secondary disease conforms to the type of the primary.

Cancer usually occurs after 40 years of age, though I have operated for cancer of the head of the pancreas at 32 years of age and rarely it has been known to occur in childhood. I have seen and personally examined considerably over 100 cases of cancer of the pancreas, in many of which the diagnosis has been subsequently confirmed by operation or by necropsy and my experience has been that loss of weight and strength with indigestion and general malaise are the first symptoms, pain being usually absent or unimportant; that when the head of the pancreas is involved jaundice rapidly ensues, the liver swells, and the gall-bladder dilates. The patient then seems almost to dissolve away, the loss of flesh being so rapid. The motions become pale, contain fat and muscle fibre if meat be taken, and the urine gives a well-marked and special pancreatic reaction. Sugar is only found when the whole gland is involved either in the malignant disease or by secondary interstitial pancreatitis of the interacinar type.

It is quite common to find in these cases evidences of pancreatitis superadded to the growth and this causes a change in the urinary reaction which may lead to an error in diagnosis unless it is borne in mind that such a sequence is possible. There is as a rule no difficulty in diagnosing cancer of the head of the pancreas from interstitial pancreatitis, as the urinary reactions are quite distinct if performed with care, and the general symptoms, especially the duration of the disease, will usually enable the diagnosis to be made. In exceptional cases, especially when the tumour is large and growing rapidly, pain may be severe and excruciating and if the stomach is invaded vomiting assumes a prominent place. The hæmorrhagic tendency, in connexion with cancer of the head of the pancreas and jaundice, is well known, but even in cancer of the body or tail of the organ a hæmorrhagic condition may ensue. Probably the excretion of lime salts from the blood may account for the hæmorrhagic condition and for the relief that can be given by the use of calcium chloride. Bleeding from the stomach or the mouth and from the intestines, or hæmorrhages under the skin are apt to occur spontaneously and to become serious or even fatal, and in case of operation, unless the blood be previously charged with lime salts, bleeding is likely to occur in the shape of persistent oozing both at the time of operating and subsequently.

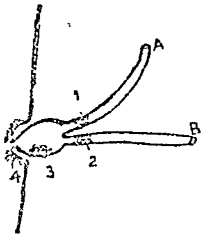
When the tumour attains any size it may be palpated from the front, but in ordinary scirrhus of the head of the pancreas no tumour can be felt, except enlargement of the gall-bladder which is generally present. Bronzing of the skin may come on if the adrenals are involved. Ascites or dropsy of the lower limbs may come on from pressure on the portal vein or inferior vena cava, or from secondary involvement of the liver, but apart from pressure slight œdema of the feet is often an early sign. Death occurs from exhaustion as a rule within a few months and is never very long delayed—in fact, cancer affecting the head of the pancreas *is more rapidly fatal than when occurring in any other* organ.

The typical clinical picture of malignant disease of the pancreas may thus be drawn: a patient suffers for a time from indefinite symptoms of digestive disturbance, then jaundice appears, coming gradually but persistently increasing; the gall-bladder is usually distended and the liver is normal or slightly enlarged. A tumour may be found in the neighbourhood of the pancreas. Cachexia rapidly develops and in some cases pain disturbs the patient's rest. There is soon a feeling of intense prostration and weakness. The fæces are massive and contain fat or fat-acids and an undue proportion of undigested muscle fibre. The urine contains albumin frequently and sugar and fat rarely. The whole clinical course is run, as a rule, within 12 months and after the appearance of jaundice within from six to eight months.

DIFFERENTIAL DIAGNOSIS.

In malignant disease of the pancreas the symptoms are not constant. The cases may be divided into three chief types: 1. Where the tumour extends to the right and compresses or occludes the common bile and the pancreatic ducts. 2. Where it takes an upward and forward direction and besides compressing the bile-duct leads to pyloric stenosis. In this case to the typical symptoms are added those of dilated stomach. 3. Where the extension is backwards, causing compression of the vena cava and of the portal veins, thus leading to an early onset of ascites and later to œdema of the lower extremities. When the body and tail of the pancreas are involved the symptoms are atypical and the development of a tumour with steady loss of strength and increasing anæmia are such as might be due to any malignant tumour outside the pancreas In the differential diagnosis of cancer of the head of the pancreas we must consider common duct cholelithiasis, interstitial pancreatitis, cancer of the common bile-duct, cancer of the liver, cancer of the pylorus, and chronic catarrh of the bile-ducts. Whenever in a patient at or past middle age jaundice comes on painlessly and becomes absolute, at the same time that the gall-bladder gradually enlarges so as to form a perceptible tumour and the patient rapidly loses flesh and strength, a diagnosis of cancer of the head of the pancreas will probably be correct. The diagnosis will be made more certain if there is an absence of tenderness below the right costal margin associated with a tumour opposite to, or above, the umbilicus, having communicated pulsation and not moving with respiration. On distending the stomach with carbon dioxide it will be found that the tumour, at the best rather indefinite, becomes hidden behind the resonant stomach and that the distended gall-bladder becomes pushed to the right. If cholelithiasis has preceded the onset of cancer the gall-bladder will not be enlarged but the rapid deterioration of health and the presence of anasarca and ascites will, as a rule, leave no doubt of the nature of the disease. In common duct cholelithiasis there is practically always a preliminary history of gall-stone attacks, though it may have been years previously. The jaundice will have come on after pain and is probably never absolute, for some bile nearly always escapes past gall-stones in the duodenum. The bile soon becomes infected and the ague-like seizures follow and an irregular temperature, at times almost resembling pyæmia. In place of a distended gall-bladder a rigid right rectus will be felt which often makes it difficult to examine the parts beneath. A tender spot will usually be found an inch above, and to the right of, the umbilicus and the pain will be found to pass backwards to the midscapular region or to a spot beneath the right shoulder-blade. Whereas in cancer of the head of the pancreas the disease is only a question of months, in cholelithiasis it may be one of years. Pancreatic catarrh or chronic pancreatitis frequently accompanies gall-stones in the common duct and clears up after their removal, but it may persist after the cause has passed away. Whenever a tumour of the head of the pancreas is felt during a gall-stone operation, especially if before middle life, hope may always be felt that the disease may be simple and may clear up by the drainage of the ducts. A long history is in favour of the simple disease, as are the presence of adhesions, the history of painful attacks, and the presence of tenderness above the umbilicus. In chronic pancreatitis it is not uncommon to find enlarged glands in the free border of the lesser omentum, but they are discrete when the disease is simple and generally confluent in cancerous affections. The jaundice may be absolute, but as a rule it is not complete. Infective cholangitis and infection of the pancreatic ducts are commonly present, as shown by the temperature and by ague-like seizures. Although the loss of flesh is marked it is less evident than in cancer of the head of the pancreas, and until the disease has existed for a longer time than cancer gives its victim there is no sign of anasarca or ascites or of enlarged abdominal veins. The gall-bladder is seldom distended, though this is not an absolute rule, as I have seen it [illegible] on duct and chronic pan- [illegible] it is often difficult to determine, but this is of no moment from a practical point of view, as surgical treatment is, as a rule, demanded in both conditions. Anæmia is much more marked in cancer of the head of the pancreas than in chronic interstitial pancreatitis. Cancer of the common duct is rare and is usually associated with gall-stones; if the disease involves the [illegible] from those of canc[illegible] it be situated above the opening of the pancreatic duct it will not interfere with the functions of the pancreas and therefore the loss [illegible] which I operated [illegible] is not a constant [illegible] d by the jaundice being absent or much less intense and by the enlargement of the liver with irregular nodules on its surface and edges. The accompanying diagram shows the positions that growths may occupy in the neighbourhood of the papilla (Fig. 15). In simple catarrhal jaundice the symptoms are almost negative except for the jaundice and loss of appetite, and the way in which it yields to treatment shows the slighter nature of the ailment. In cancer of the pylorus the predominance of gastric symptoms and the dilatation of the stomach with absence of free hydrochloric acid and presence of blood in the vomit usually enable a diagnosis to be made, but it should not be forgotten that cancer of the pylorus and of the head of the pancreas frequently coexist. In all these *cases the urinary test affords most valuable help in diagnosis.*

FIG. 15.



1. Growth commencing in common bile-duct A. 2. Growth commencing in Wirsung's duct B. 3. Growth commencing in diverticulum. 4. Growth commencing on papilla.

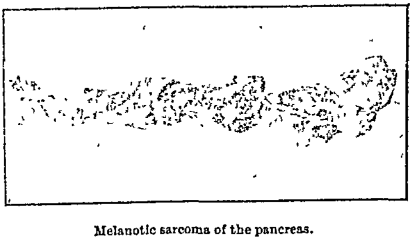
TREATMENT.

Medical treatment must be purely symptomatic; morphine if needed for the relief of pain; calcium chloride for the prevention of hæmorrhage; pankreon tablets or liquor pancreaticus for the digestion of food; and other remedies for symptoms as they arise. Surgical treatment is not very hopeful and has usually been undertaken under the idea that the cause of the jaundice might be a removeable one or that drainage of the bile-ducts might afford relief to the jaundice, but if the disease has involved the head of the pancreas it is hopeless however treated. Treatment may be radical or palliative. Ruggi of Bologna removed through the loin a cancer of the pancreas weighing 23 ounces. It was probably growing from the tail of the gland. Complete recovery followed and the patient was well for three months, after which secondary disease developed and the patient died at the end of six months. Professor Ruggi himself furnished me with these details. Cades' was the second successful case, in 1895, a tumour of the tail of the pancreas of the size of a child's head being removed. Terrier in 1892 removed a tumour weighing five pounds but lost his patient. Of 16 operations for removal of solid tumours of the pancreas, eight recovered, which, considering the difficulty of the operation and the depth of the organ to be operated on, is better than one would have expected. Successful pancreatectomies it will be seen are exceptional cases and are only feasible where the growth is not involving the head of the gland; they, however, clearly demonstrate that a tumour of the body or of the tail of the pancreas may be removed with equal chances of recovery, and should the disease be primary and no secondary growths or glandular involvement have occurred, great prolongation of life is quite possible. Of the palliative operations, cholecystotomy and cholecystenterostomy for the relief of jaundice in cancer of the head of the pancreas, I can speak about very decidedly, as I have operated on 28 cases, all the patients being extremely ill at the time of operation. Many of these cases occurred when there was a difficulty in making a diagnosis between cancer of the head of the pancreas and gall-stones in the common duct or between cancer and interstitial pancreatitis, difficulties which have been overcome recently. Of the 15 cases in which the gall-bladder was drained eight recovered from the operation, the longest survival being eight months, but the average survival being about four months; of the six cholecystenterostomies two recovered and the duration of life was only a few weeks. Even a simple exploratory operation in these cases is attended with danger, for out of six cases four only recovered from operation. Dr. Murphy of Chicago was kind enough to furnish me with a report of his statistics of cholecystenterostomy up to 1897. Of 67 non-malignant cases there had only been three deaths, but of his 12 malignant cases 10 died, giving a mortality of 83·3 per cent. Thus it will be seen that any palliative operation for the relief of cancer of the head of the pancreas associated with jaundice is useless, as, even if recovery occurs, life is not prolonged to any great extent.

SARCOMA.

Primary sarcoma of the pancreas is undoubtedly rare, though secondary disease, especially of the melanotic type, seems to be less uncommon. I have found examples of sarcoma in several of the museums, photographs of which I have obtained and will now show on the screen. The first is of melanotic sarcoma from the Hunterian Museum, the specimen being on the table (Fig. 16). It was taken from a girl, aged 20 years, and was secondary to a melanotic growth in the eye which was removed three years before her death. The next specimen shows melanotic sarcoma with fat necrosis. The next is from St. George's Hospital, No 201 E, and shows a secondary sarcoma, the primary growth being in the thymus gland. The next specimen is a very large spindle-celled sarcoma from University College Hospital Museum, No. 3200 (Fig. 17). The growth has

FIG. 16.



Melanotic sarcoma of the pancreas.

completely involved the gland and has left no trace of gland tissue. The next specimen (Fig. 18) I throw on the screen is on the table, No. 2836 A. It was removed from the tail of the pancreas but the child succumbed shortly after the operation. Operation for sarcoma of the pancreas is uncommon, though the few cases operated on prove that if the tumour be in the tail of the pancreas the case is one amenable to surgical treatment. I explored the abdomen in one case of the kind but found the disease too extensive for removal. Kronlein in 1894 removed a tumour of the size of the fist but the patient died seven days later. A tumour which was successfully removed by Briggs proved to be sarcomatous degeneration of an echinococcus cyst.

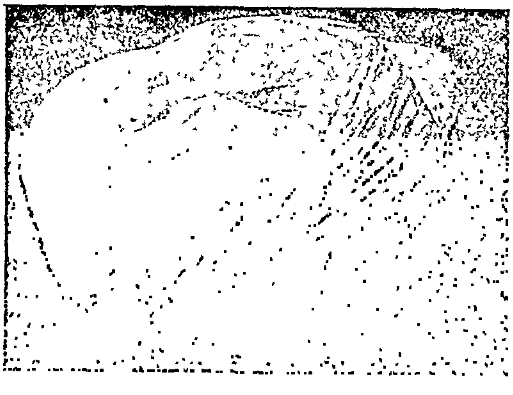
Spindle-celled sarcoma of the pancreas.

FIG. 18.



Sarcoma removed from the tail of the pancreas.

Mr. President, I must apologise for the imperfect manner in which I have been able to deal with the several subjects in my last lecture but want of time has compelled me to cut out much of what I should like to have said. I hope, however, that my lectures will be the means of exciting more general interest in the surgery of the pancreas, a subject which I feel is much more worthy of attention than hitherto has been accorded to it. It only remains for me to thank you for the patient hearing and the kindly interest that have been shown in what I have had to say and at the same time I would thank the Council of the Royal College of Surgeons of England for the honour they have done me in electing me a third time to hold this important chair.

ON THE PRECIPITIN OF COBRA VENOM.

BY GEORGE LAMB, M.D. GLASG.,
CAPTAIN, INDIAN MEDICAL SERVICE; ASSISTANT DIRECTOR, PASTEUR INSTITUTE OF INDIA.

SECOND COMMUNICATION.

IN a previous communication[1] on the above subject it was shown that the serum of a rabbit which had been subjected to gradually increasing doses of pure unheated cobra venom possesses the property of causing a coagulum or precipitum when mixed in suitable proportions with solutions of suitable strength of this venom; that, in short, the rabbit reacts to injections of the proteids of cobra venom exactly in the same way—that is, by the formation of specific precipitins—in which it reacts to injections of various other proteid substances, such as the proteids of serum, egg albumen, Witte's peptone, &c. It was further demonstrated that when this immune serum and a solution of cobra venom of definite strength were mixed in suitable proportions both the precipitin and the precipitable proteids were entirely used up. Taking advantage of this fact we were able to give a numerical expression to the precipitin value of the serum in terms of the amount of cobra venom which a given quantity of serum would exactly neutralise. It was on this account suggested that by this method we might possibly have at hand an easy and ready means of standardising an antivenomous serum. In conclusion, it was shown in this communication that while the serum of a rabbit immunised with cobra venom gave with the proteids of daboia venom a copious precipitum, indistinguishable, in fact, from the precipitum given with cobra venom itself, no coagulum was obtained when this serum was mixed with the venoms of three other species of snakes—namely, (1) echis carinata, (2) bungarus fasciatus, and (3) hoplocephalus curtus.

In the present communication it is proposed further to extend these observations in several directions which were indicated in the previous paper. It is, however, as well to mention at the outset that several of the problems which were then mentioned as awaiting solution have still to be left undecided. In the first place, the observations summarised above have been extended by testing a cobra venom serum—that is to say, the serum of a rabbit highly immunised with pure unheated cobra poison—with the venoms of five other species of snakes—namely, (1) naja bungarus; (king cobra); (2) bungarus cœruleus (common krait); (3) enhydrina valakadien (a common sea snake); (4) trimeresurus gramineus (green pit viper); and (5) crotalus adamanteus (Californian rattlesnake).[2] In order to make these observations as conclusive as possible two methods of technique were employed in each instance. The first method consisted in mixing different proportions of serum with one part of venom solution of definite strength—namely, 0·05 per cent. In the second method three parts of serum were mixed with one part of venom solution of different strengths. In all cases these mixtures were effected by means of Wright's tubes of large calibre. The preparations were then kept at from 35° to 37° C. for about 20 hours, when the results were recorded. A reference to the protocols (Tables I. and II.) will show that while no coagulum was formed with three of the poisons mentioned above—namely, the venoms of naja bungarus, of bungarus cœruleus, and of crotalus adamanteus—and only a trace of precipitum with the venom of enhydrina valakadien, a marked precipitum was obtained with the poison of *trimeresurus gramineus*. This precipitum, however, was not nearly so copious as those got with cobra venom itself and with daboia venom. Taking the above results along with those which were contained in my previous communication we can divide the venoms which have been tested with a serum prepared by injecting rabbits with pure unheated cobra poison into three groups as follows:—

GROUP A. *Venoms which give a copious precipitum.*—(1) Venom of naja tripudians (cobra); and (2) venom of vipera Russellii (daboia).

---

[1] THE LANCET, August 16th, 1902, p. 431.

[2] The king cobra venom was obtained from two snakes the property of the Natural History Society, Bombay; the sea-snake venom from Mr. Peal, Calcutta; and the crotalus venom from Professor S. Flexner, Philadelphia. I am much indebted for these gifts. The other poisons were collected under my own supervision.

GROUP B. *Venoms which give a marked or trace of precipitum.*—(3) Venom of trimeresurus gramineus (green pit viper); and (4) venom of enhydrina valakadien (common sea snake).

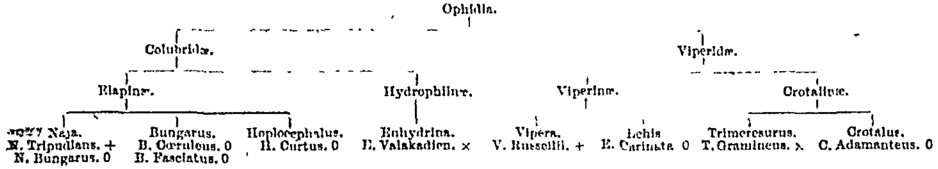
GROUP C. *Venoms which give no precipitum.*—(5) Venom of naja bungarus (king cobra), (6) venom of bungarus cœruleus (common krait), (7) venom of bungarus fasciatus (banded krait), (8) venom of hoplocephalus curtus (tiger snake), (9) venom of echis carinata (phoorsa), and (10) venom of crotalus adamanteus (Californian rattlesnake).

With a view of seeing if the venoms which give a precipitin reaction with a cobra venom immune serum are derived from species which are more closely related in the animal kingdom to the cobra than are the species the poisons of which do not give this reaction, the accompanying diagram, which shows at a glance the position of these several species among the ophidia, has been constructed.

language of Ehrlich's side-chain theory, we can say that the cobra's cells must be deficient in the specific receptors which are present in the cells of animals susceptible to the poison and which allow of the poison being bound to the cells. It would be interesting in this connexion to ascertain whether the central nervous tissues of the cobra were able to neutralise the poison in vitro in the same manner as has been shown in the case of those tissues of susceptible animals and also whether the cobra's red cells were susceptible to the poison in the same way as the red cells of other animals—that is to say, were hæmolysed by the venom. Unfortunately, however, I have no living cobras at present at my disposal.

The second series of observations now under consideration was made with cobra venom immune serum and cobra serum. In these experiments also two methods of technique were employed. In one method the cobra venom immune serum was mixed in varying proportions with one part of cobra serum. These proportions varied from 10 to 1 to 1 to 1. In the other method four parts of cobra venom serum were mixed with one part of different dilutions of cobra serum, the dilutions varying from two-fold to 1024-fold. In both instances the cobra venom immune serum was the serum of a rabbit highly immunised with cobra venom. Not a trace of coagulum was observed in any of these preparations. We can therefore conclude that the serum of a rabbit highly immunised with cobra venom contains no precipitin for cobra serum.

DIAGRAM SHOWING THE PRECIPITIN REACTION IN DIFFERENT SPECIES.



+ Give a copious precipitum. × Give a marked or trace of precipitum 0 Give no precipitum.

A study of this diagram will at once make it apparent that this venom precipitin test affords no indication of the closeness of species relationship. Thus, for example, it will be noted on the one hand that the venom of naja bungarus, a species belonging to the same genus as the cobra, gives no precipitum with a cobra venom immune serum, and, on the other hand, that the venom of vipera Russellii, a species belonging even to a different family from the cobra, gives a copious precipitum with cobra venom immune serum. These observations therefore are not in accord with the similar observations which have been made by Nuttall and others working with immune sera prepared by injections of the sera of different species of animals and which went to show that a serum prepared by injections of the serum of one species of animal gave a certain amount of precipitum with the sera of animals closely related to the animal the serum of which was used for the injections and gave no precipitum with the sera of animals more distantly related. The same law does not evidently hold good for the venoms of the poisonous snakes. Further, these results show that great differences must exist between the proteids of the poisons of the several species of snakes, differences which must be kept carefully before the mind when dealing with the physiological actions of the venoms of the several species.

In the second place, I have now to pass on to the consideration of some observations which were made with the serum of the cobra itself and with the serum of a rabbit which had been treated by repeated injections of cobra serum. The cobra serum was obtained by opening the thorax of living snakes, cutting the aorta across, and catching the blood from the cut end. After allowing the blood to clot a clear serum was got by centrifugalisation. The first series of experiments was made with a view of ascertaining if cobra serum contained any precipitin for cobra venom. Two methods of experimentation were employed. In one method four parts of serum were mixed with one part of cobra venom solution of a strength varying from 1 per cent. to 0·0078 per cent. In the other method varying proportions of the serum were brought in contact with one part of cobra venom solution of fixed strength—namely, 0·05 per cent. The proportions of serum to venom solution varied from 10 to 1 to 1 to 2. As no trace of coagulum was obtained in any of these preparations the experiments are not given in detail in the protocols.

Such a result was only to be expected. It has been shown by several observers that the cobra is immune to its own poison and that this immunity is not due to the presence of any antitoxic substances in its blood. It is therefore evident that, although constant absorption of the poison must be taking place, neither antitoxin nor precipitin is prepared. Stating the conclusion to be drawn from these facts in the

The third series of experiments was made with a view of ascertaining if the serum of a rabbit which had been treated with injections of cobra serum contained any precipitin for this serum as well as for daboia serum. A rabbit was treated with three subcutaneous injections of fresh cobra serum. These injections, amounting to 11 cubic centimetres in all, were made at intervals of about ten days. The serum of the rabbit was collected eight days after the last injection. It was then tested against both cobra serum and daboia serum, the latter of which was obtained in the same manner as has been described in the case of the cobra serum. A reference to the protocols (Tables III. and IV.) will show that a very copious and well marked precipitum was obtained with cobra serum, while a much less marked but still distinct reaction was obtained with daboia serum. The difference between these two reactions was very apparent and is well shown by the fact that in many of the preparations w [illegible] with cobra serum [illegible] tation was seen in [illegible] serum.

It was now of interest to ascertain if this rabbit's serum, prepared with cobra serum, gave any precipitin reaction with cobra venom. An experiment made with this end in view is detailed in Table V. of the protocols. It will be seen from this table that a well-marked precipitin reaction took place between these two substances. The reaction, however, was not so well marked as that between cobra venom immune serum and cobra venom. It is difficult in the present state of our knowledge as regards proteid precipitin and proteid assimilation to reconcile the two facts now demonstrated—namely, that a serum prepared by injections of cobra venom contains no precipitin for cobra serum but that a serum prepared by injections of cobra serum gives a well-marked precipitum with cobra venom. I am afraid I can at present offer no suitable expl [illegible]

In my previous [illegible] ject under discussion I was able [illegible] the serum of a rabbit immunised with cobra venom, it was possible to give a numerical expression to the [illegible] of this serum by estimating with what [illegible] nd venom solution of known strength both the precipitin and precipitable substances were used up. Further, it was suggested that by such an estimation of the precipitin value of a serum a method of standardising an antivenomous serum might be elaborated. In the third place, I have now to put on record some observations which show definitely that the hope which was then expressed cannot be fulfilled. In the course of these experiments some interesting points were settled as regards the relationship of precipitin to antitoxin. These points will also now receive attention. The first experiments were made with the serum of an ass which had received over a period of six months repeated injections of pure unheated cobra venom. The antitoxic value of this serum was estimated by experiments on rats after the method already described.[3] A reference to the protocols (Table VI.) will show that one cubic centimetre of this serum was able to neutralise 0 07 milligramme of cobra venom. On experimenting now to ascertain the precipitin value of the serum it was found that it contained no, or only the merest trace of, precipitin (*vide* protocols, Table VII.). This result at once suggested that the formation of antitoxin is independent of the formation of precipitin. As, however, the antitoxic value of this serum was by no means high, it was necessary to make further experiments with a serum of much greater antitoxic power. Further observations were therefore made with the serum of a horse (Horse A) which had been treated over a period of nearly two years with repeated subcutaneous injections of pure unheated cobra venom. The antitoxic value of this serum was determined in a manner similar to that used in the case of the serum of the ass, small rabbits, however, being employed instead of rats. It will be seen from the protocols (Table VIII.) that one cubic centimetre of this serum was able to neutralise at least 1·2 milligrammes of cobra venom, an antitoxic value nearly 20 times greater than that of the serum of the ass. An attempt was next made to estimate the precipitin value of the serum. If the results obtained in these experiments (protocols, Tables IX. and X.) be compared with the results of the estimation of the precipitin content of the serum of a rabbit highly immunised with cobra venom (protocols, Tables XIV.–XVII.) it will be at once seen that this horse's serum contained evidently such a small amount of precipitin that there was no possibility of making an accurate estimation of it after the manner I have already described.[4] First, it appears from these two observations that neither the ass nor the horse, in comparison with the rabbit, is a suitable animal for the preparation of a precipitin for cobra venom. This conclusion is substantiated by experiments which were made with the serum of another horse (Horse B) which had been subjected over a period of 15 months to repeated injections of pure unheated cobra venom. The serum of this horse was also found to contain very little precipitin. As the experiments gave practically the same results as those obtained with the serum of Horse A they are not detailed in the protocols. It is only necessary to add that the reaction was not quite so well marked as in the case of the serum of Horse A, but it was sufficient to show that a certain, though small, amount of precipitin was present. Secondly, it appears from these two observations that the elaboration of precipitin is quite independent of the formation of antitoxin which results from injections of pure cobra venom. To this point we shall return in a moment. It is now, however, evident from these two facts—namely, that the horse, the animal most suitable for the preparation of an antitoxic serum, reacts only slightly to the injection of cobra venom by the formation of specific precipitin and that the formation of precipitin seems to be quite independent of the formation of antitoxin—that the suggestion I previously put forward that this precipitin test might furnish us with a method of standardisation of antivenomous sera cannot be realised.

A further proof of the fact that the formation of precipitin is quite independent of the elaboration of antitoxin is afforded from the examination of the serum of a horse (Horse C) which had been treated for a period of 22 months by repeated injections of pure cobra venom heated for half an hour at 72° C. The antitoxic value of this serum, as estimated on small rabbits (*vide* protocols, Table XI.), was found to be considerable, one cubic centimetre of serum being able to neutralise about one milligramme of unheated cobra venom. On testing for the presence of precipitin in this serum it was found to contain practically none of this substance (protocols, Tables XII. and XIII.). Further, I tested the sera of two horses which were in the process of immunisation also with pure cobra venom heated for half an hour at 72° C. One of these horses had been under treatment for a period of six months and the other for a period of three months. Neither of these sera contained even a trace of precipitin. Now we have seen above that the serum of a horse immunised with unheated cobra poison contains precipitin, although the quantity, in comparison with the amount present in the serum of an immunised rabbit, is small. It would appear, therefore, from these last observations that when the solution of venom is heated at 72° C. before injection the elaboration of precipitin does not take place in the case of the horse. In conclusion, I have now to bring forward the result of an observation which also bears on the question of the elaboration of precipitin being independent of that of antitoxic substances inasmuch as it consists of some estimations made at intervals of the amount of precipitin present in the serum of a rabbit which was treated over a period of 19 months with gradually increasing doses of pure unheated cobra venom.

Two methods were used to form an estimate of the amount of precipitin in this serum. Linossier and Lemoine,[5] as a result of a long series of experiments, pointed out that in order to give a numerical expression to the precipitin value of a serum it was only necessary to ascertain at what maximum dilution the precipitable proteids begin to be precipitated under the action of a known precipitin, the proportion of serum to the various dilutions remaining the same in all the preparations. On this principle one of the methods employed in my experiments was founded. Further, I also used the method described in my previous communication—namely, the method of estimating with what proportion of serum and venom solution of known strength a neutral solution was obtained; that is to say, a solution containing neither precipitin nor precipitable substances. The first precipitin estimation of this rabbit's serum was made after the animal had been under treatment for a period of five months, during which period it had received a total amount of 0·0151 gramme of venom. The last injection made before this observation was one of 0·0018 gramme—that is, about six lethal doses. It will be seen from the protocols (Table XIV.) that at this period of immunisation when three parts of serum were mixed with one part of venom solutions of different strengths a coagulum began to appear with a solution of a strength of 0·00625 per cent. Further, it will be seen (Table XV., *a* and *b*) that the neutralisation point was reached when six parts of serum were mixed with one part of venom solution of 0·05 per cent. strength. Various observations were made at intervals after this primary estimation, but at no time was any increase of this precipitin value of the serum found to be present. At the end of 19 months when the rabbit had received as a last dose 0·008 gramme, equivalent to about 26 lethal doses, and a total amount of 0·151 gramme of venom, the precipitin value of the serum remained practically the same as it was 14 months previously (protocols, Tables XVI. and XVII.). If anything it had slightly decreased. Thus, when three parts of serum were mixed with venom solutions of different strengths only a mere trace of coagulum was observed in the preparation containing a solution of 0·00625 per cent. strength and the neutralisation point was reached when eight parts of serum were mixed with one part of venom solution of 0·05 per cent. strength. From these observations we can conclude that the precipitin value of the serum of a rabbit undergoing immunisation with pure unheated cobra venom quickly reaches a maximum and remains at or about this level during the process. Although the antitoxic value of this particular serum was not at any time estimated, we can take it from *a priori* reasons and from the facts that the animal stood well the gradually increasing doses of venom and was at the time of the last experiment in a condition of high immunisation, that the serum was at the end of the process of high antitoxic value. These observations therefore lend support to the conclusion arrived at already—namely, that the elaboration of the precipitin of cobra venom is quite independent of the formation of true antitoxin.

PROTOCOLS.

In all the precipitin experiments detailed hereafter the mixtures were effected by means of Wright's sedimentation tubes of large calibre. The tubes after being sealed were kept at from 35° to 37° C. for 20 hours, when the results were recorded. In all the tables the following signs are used: [illegible] m; × signifies a marked pre- [illegible] trace of precipitum; † signi- [illegible] cipitation; and 0 signifies no precipitum or opacity.

TABLES I. AND II.—*Experiments with Cobra Venom Serum and other Varieties of Snake Venom.*

The serum which was used was that of a rabbit which had been highly immunised by subcutaneous injections of pure unheated cobra poison. The snake venoms were obtained from (1) naja bungarus (king cobra) = N.B.V.; (2) bungarus cœruleus (common krait) = B.C.V.; (3) enhydrina valakadien (common sea snake) = E.V.V.; (4) trimeresurus gramineus (green pit viper) = T.G.V.; and (5) crotalus adamanteus (Californian rattlesnake) = C.A.V. Two series of experiments were made. In the first series varying proportions of serum were mixed with one part of a 0·05 per cent. solution of each poison. The following were the results obtained:—

TABLE I.

Proportion of serum to venom solution (0 05 per cent.)	N.B.V.	B C.V.	E.V.V.	T.G.V.	C.A.V.
12-1	0	0	0	*	0
10-1	0	0	0	*	0
8-1	0	0	0	×	0
6-1	0	0	*	×	0
4-1	0	0	*	*	0
2-1	0	0	*	*	0
1-1	0	0	0	*	0

In the second series of experiments three parts of serum were mixed with one part of a solution of different strengths of each variety of poison as indicated below. The dilutions of venom were made with normal saline solution. The following were the results obtained:—

TABLE II.

Serum = 3 parts; venom solution = 1 part.

Strength of venom solution per cent.	N B.V.	B.C.V.	E.V.V.	T.G.V.	C A.V.

0·025	0	0	*	*	0
0 0125	0	0	*	*	0
0 00625	0	0	0	0	0
0 003125	0	0	0	0	0

TABLES III. AND IV.—*Experiments with the Serum of a Rabbit treated with Cobra Serum and Cobra and Daboia Sera.*

A rabbit was treated with three subcutaneous injections of two cubic centimetres, four cubic centimetres, and five cubic centimetres of cobra serum at intervals of ten days. Eight days after the last injection its serum was collected. Two methods of technique were employed. In the first series of observations varying amounts of the treated rabbit's serum were mixed with one part of both cobra serum and daboia serum. The following was the result:—

TABLE III.

Proportion of rabbit's serum to snake serum.	Cobra serum.	Daboia serum.
8-1	+	†
6-1	+	†
4-1	+	†
2-1	+	†
1-1	+	†

In the second series of observations three parts of the treated rabbit's serum were mixed with one part of increasing dilutions of both cobra serum and daboia serum. The dilutions were made with normal salt solution. The following results were obtained:—

TABLE IV.

Treated rabbit's serum = 3 parts. Diluted snake serum = 1 part.

Dilutions of cobra or daboia serum.	Cobra serum.	Daboia serum.
2 fold	+	†
4 ,,	+	†

128 ,,	×	*
256 ,,	×	*
512 ,,	*	0
1024 ,,	*	0

TABLE V.—*Experiment with the Serum of a Rabbit treated with Cobra Serum and Cobra Venom.*

The same rabbit's serum as was used in the previous observations was employed. Varying amounts of serum were mixed with one part of a cobra venom solution of fixed strength (0·05 per cent.). The following results were obtained:—

Parts of treated rabbit's serum.	Parts of cobra venom solution (0 05 per cent.).	Result.
8	1	*
6	1	*
4	1	+
2	1	×
1	1	×
1	2	×

TABLE VI.—*Experiments to Estimate the Antitoxin Value of the Serum of an Ass treated with repeated Injections of pure unheated Cobra Venom.*

The ass had received over a period of six months repeated injections, gradually increasing in amount, of pure unheated cobra venom. The animals used for testing the serum were rats of about 115 grammes in weight. The minimum lethal dose of cobra venom for a rat of this size is about 0·05 milligramme. The test dose of venom used was 0 25 milligramme—that is to say, five lethal doses. This test dose and varying amounts of serum were mixed in vitro and allowed to stand for half an hour at laboratory temperature (25° C.). The mixtures were injected subcutaneously. The following was the result:—

Animal.	Cobra venom in milligrammes.	Serum.	Result.
Rat 1	0·25	1 0 c.c.	Died in four hours.
,, 2	,,	2 0 ,,	,, 24 ,,
,, 3	,,	2 5 ,,	,, 44 ,,
,, 4	,,	3 0 ,,	No symptoms.
,, 5	,,	3·5 ,,	
,, 6	,,	4 0 ,,	
,, 7	,,	4 5 ,,	
,, 8 (control) ...	,,	*Nil.*	Died in three hours.

From the above series of experiments we can conclude that three cubic *centimetres of serum* could neutralise at least 0·25 – 0 04 = 0·21 milligramme of venom—that is, that one cubic centimetre could neutralise 0·07 milligramme.

TABLE VII.—*Experiment to Show the Precipitin Reaction of the Serum of an Ass treated with repeated Injections of pure unheated Cobra Venom.*

The serum used was the same as that employed in the previous series of observations. The method now employed to test the precipitin reaction was that method in which different proportions of serum are mixed with one part of 0·05 per cent. solution of cobra venom. The following was the result obtained :—

Parts of serum.	Parts of cobra venom (0 05 per cent.)	Result.
10	1	0
8	1	0
6	1	0
4	1	0
2	1	0
1	1	0
1	2	*

TABLE VIII.—*Experiments to Estimate the Antitoxin Value of the Serum of Horse A.*

This horse had been treated over a period of nearly two years with repeated subcutaneous injections, gradually increasing in amount, of pure unheated cobra venom. The test dose of cobra venom, left unheated, now used was two milligrammes for rabbits of about 650 grammes in weight—namely, about ten lethal doses. The minimum lethal dose, by subcutaneous injection, for rabbits of this sample of venom was about 0 35 milligramme per kilogramme. The test dose and different amounts of serum were mixed in vitro and the mixtures were allowed to stand for half an hour at laboratory temperature. They were then injected subcutaneously. The following were the results :—

Animal.	Weight (grammes)	Cobra venom in milli-grammes	Serum.	Result.
Rabbit 1	610	2	1·0 c c.	Died in 2½ hours.
,, 2	680	,,	1·3 ,,	,, 12 ,,
,, 3	615	,,	1 4 ,,	,, 13½ ,,
,, 4	720	,,	1·5 ,,	No symptoms.
,, 5	685	,,	1·6 ,,	,,

From these experiments it will be seen that 1·5 cubic centimetres of serum neutralised 2 – 0 2 (maximum non-lethal dose for rabbit of 720 grammes) = 1·8 milligrammes. Therefore one cubic centimetre could neutralise 1·2 milligrammes.

TABLES IX. AND X.—*Experiments to Show the Precipitin Reaction between the Serum of Horse A and Cobra Venom.*

The same serum as was used for the experiments detailed above was employed to test the precipitin reaction. Two methods of technique were employed. In the first series of experiments varying proportions of serum were mixed with one part of a 0 05 per cent. solution of cobra venom. The following results were obtained :—

TABLE IX.

Parts of serum.	Parts of cobra venom solution (0 05 per cent.).	Result.
10	1	0
8	1	0
6	1	0
4	1	*
2	1	+
1	1	*
1	2	†

In the second series of experiments three parts of serum were mixed with one part of cobra venom solution different strengths. The following was the result :—

TABLE X.

Parts of serum = 3 ; parts of C. V. solution = 1.

Strength of cobra venom solution.	Result.
0·2 per cent.	*
0·1 ,,	+
0·05 ,,	*
0·025 ,,	0
0·0125 ,,	0
0 00625 ,,	0
0 003125 ,,	0

TABLE XI.—*Experiments to Estimate the Antitoxin Val of the Serum of Horse C.*

This horse had been treated over a period of 22 mont with gradually increasing doses of pure cobra venom heat for half an hour at 72° C. The technique used for t estimation was the same as was used in the experimen detailed in Table VIII. The following were the results :—

Animal.	Weight (grammes).	Cobra venom in milli-grammes.	Serum.	Result.
Rabbit 1	750	2	1·0 c c.	Died in 3 hour
,, 2	580	,,	1·3 ,,	,, 3 ,,
,, 3	500	,,	1·6 ,,	,, 18 ,,
,, 4	780	,,	1 8 ,,	No symptoms
,, 5	700	,,	2 0 ,,	,,

From these experiments it will be seen that 1·8 cubic cent metres of serum neutralised 2 – 0 2 = 1·8 milligrammes venom. Therefore one cubic centimetre could neutralise o milligramme.

TABLES XII. AND XIII.—*Experiments to Show the Pr cipitin Reaction between the Serum of Horse C and Cob Venom.*

The same serum as was used in the experiments detaile above was now employed to test the precipitin reactio Two methods of technique were employed. In the first seri of experiments varying proportions of serum were mixe with one part of a 0 05 per cent. solution of cobra venor The following results were obtained :—

TABLE XII.

Parts of serum.	Parts of cobra venom solution (0 05 per cent.)	Result.
10	1	0
8	1	0
6	1	
4	1	
2	1	0
1	1	Slight opacity.

In the second series of experiments three parts of seru were mixed with one part of cobra venom solution o different strengths. The following was the result :—

TABLE XIII.

Parts of serum = 3 ; parts of C.V. solution = 1.

Strength of C. V. solution.	Result.
0 2 per cent	
0·1 ,,	Slight opacity
0 05 ,,	0
0 02 ,,	0
0 0125 ,,	
0 00625 ,,	0

From these observations it can be concluded that this serum contained practically no precipitin.

TABLES XIV. TO XVII.—*Experiments to Estimate the Amount of Precipitin in the Serum of a Rabbit at Different Stages in the Process of Immunisation with Cobra Venom.*

The rabbit was treated over a period of 19 months with subcutaneous injections of gradually increasing doses of pure unheated cobra venom. The first estimation of the precipitin content of the serum was made after the rabbit had been under treatment for five months, having received during this time 0·0151 gramme of venom. Two methods of appraising the precipitin value of the serum were employed. 1. In the first instance three parts of serum were mixed with one part of venom solution of different strengths. The following were the results:—

TABLE XIV.

Parts of serum = 3; parts of C.V. solution = 1.

Strength of venom solution.	Result.
0·1 per cent.	+
0·05 ,,	+
0·025 ,,	+
0·0125 ,,	+
0·00625 ,,	*
0·003125 ,,	0

2. In the second instance varying proportions of serum were mixed with one part of venom solution of fixed strength (0·05 per cent.). The following result was obtained:—

TABLE XV. (*a*).

Parts of serum.	Parts of venom solution (0·05 per cent.).	Result.
12	1	+
8	1	+
6	1	+
4	1	+
2	1	×
1	1	

The clear supernatant fluid in each of these tubes was then obtained by simply filing off the end of the tube with the contained precipitum. It was divided into two portions. To one portion was added an equal quantity of cobra venom solution (0·05 per cent.) and to the other portion was added an equal amount of the same serum as was used in the first series of experiments. The results were as follows:—

TABLE XV. (*b*).

Proportion of serum to venom solution in original preparation.	C.V. solution (0·05 per cent.).	Serum.
12–1	*	0
8–1	*	0
6–1	0	0
4–1	0	*
2–1	0	×
1–1	0	+

It is evident, then, that the neutralisation point was reached when six parts of serum were mixed with one part of the venom solution (0·05 per cent.). The last estimation of the precipitin value of this rabbit's serum was made after it had been under treatment for 19 months, having received during this period 0·151 gramme of venom. The same method was used to estimate the precipitin value of the serum as in the previous observation. The results were as follows.

TABLE XVI.

Parts of serum = 3; parts of C.V. solution = 1.

Strength of venom solution.	Result.
0·1 per cent.	×
0·05 ,,	+
0·025 ,,	*
0·0125 ,,	*
0·00625 ,,	*
0·003125 ,,	0

TABLE XVII. (*a*).

Parts of serum.	Parts of cobra venom solution (0·05 per cent.)	Result.
12	1	+
10	1	+
8	1	+
6	1	+
4	1	×
2	1	×
1	1	*

The supernatant fluid in each tube was treated in the same manner as in the experiments detailed above (Table XV., *a*). The following was the result:—

TABLE XVII. (*b*).

Proportion of serum to venom solution in original preparation.	C.V. solution (0·05 per cent.)	Serum.
12–1	*	0
10–1	*	0
8–1	0	0
6–1	0	*
4–1	0	*
2–1	0	*
1–1	0	×

It is evident, then, that the neutralisation point was, in this case, reached when eight parts of serum were mixed with one part of venom solution (0·05 per cent.)

Kasauli, India.

ON A NEW METHOD OF TESTING THE BLOOD AND THE URINE,

WITH SPECIAL REFERENCE TO THE DETERMINATION OF THE EXCRETORY EFFICIENCY OF THE KIDNEY.

By A. E. WRIGHT, M.D. DUB.,
LATE PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY; PATHOLOGIST TO ST MARY'S HOSPITAL, PADDINGTON, W.;
AND
J. NEWPORT KILNER, M.B. LOND.,
ASSISTANT MEDICAL OFFICER, BENGAL AND NAGPUR RAILWAY.

(*From the Pathological Laboratory St. Mary's Hospital, and the Physiological Laboratory, University of London.*)

THE examination of the urine for albumin is a very indirect, ineffective, and often fallacious method of obtaining information with regard to the excretory efficiency of the kidney. While it is capable of revealing leakage of the albuminous substances from the blood into the urine it tells us nothing with regard to the excretion of the salts and products of metabolism generally into the urine. This information is furnished by comparative cryoscopic examinations of the urine and of the blood from which that urine has been elaborated. These examinations, involving as they do not only resort to complicated and delicate apparatus but also the employment of a comparatively large quantity of blood, are impracticable in connexion with ordinary clinical work. The difficulties which are associated with cryoscopic work may be avoided by the method described below. The information which it furnishes seems likely to be of value alike to the clinician, the operating surgeon, and the medical officer who has to deal with life insurance.

Principle of the method.—A standard quantity of normal red corpuscles suspended in a measured volume of salt solution of a standard strength furnishes a test fluid. The urine, or as the case may be the blood fluid (serum) from which that urine is derived, is mixed in progressive dilutions in a capillary tube with measured volumes of the standard suspension of red blood corpuscles. The point is determined at which the urine or serum has been so far diluted as to allow of complete hæmolysis of the standard suspension of red corpuscles. From these data taken in association with the data obtained on diluting the suspension of corpuscles with progressive dilutions of a decinormal sodium chloride solution, the concentration of the serum and urine is calculated. The quotient obtained by dividing the latter by the former is denoted "*the excretory quotient*."

Procedure employed in making the suspension of red corpuscles.—A stout piece of glass tubing about 2 centimetres in thickness is taken. It is drawn out in the blow-pipe flame into a narrower stem about 5 centimetres in length and 0·5 centimetre thick. The extremity of this stem is again drawn out into a still narrower tube. A graduation mark is now placed with a glass writing pencil upon the stem at a distance of, say, 1·5 centimetres from its extremity. A watery fluid or mercury is now drawn in through the capillary of the extremity tube until the stem is filled in up to the fiduciary mark. Two further graduation marks are now to be added, the points of application of these marks being found by displacing the column of fluid along the capillary stem until its distal limit corresponds in each case to the preceding fiduciary mark. Blood obtained from a prick in the finger is now filled in through the capillary orifice. When the upper limit of the column of blood stands level with the second division mark the orifice of the tube is introduced into a vessel containing decinormal sodium chloride solution and the fluid is aspirated into the tube until a 50- to 100-fold dilution of the blood has been effected. The extremity of the tube having been sealed the centrifuge is now brought into use and the centrifugalisation is continued until the corpuscles have all been driven down below the upper of the three graduation marks. The supernatant fluid is now pipetted off and, if necessary, decinormal solution is added until the upper limit of the fluid stands level with the upper graduation mark. The fluid and the red corpuscles are now thoroughly mixed up together. Inasmuch as two volumes of normal blood furnish one volume of corpuscles and inasmuch as the plasma has been diluted to practically an unlimited extent the suspension which has been obtained may without appreciable error be said to correspond to one volume of corpuscles completed to three volumes by decinormal salt solution.

Standardisation of the corpuscular suspension.—In the case where we desire to compare among themselves a number of separate observations on the blood or urine undertaken upon different days or with the bloods of different persons it is essential to determine in each case how far the standard suspension requires to be diluted before complete hæmolysis is obtained. For this purpose we make, employing a capillary pipette and the technique of dilution described in previous papers,[1] a series of progressive dilutions of our decinormal sodium chloride solution. Usually it will suffice if we make a four-fold, five-fold, and six-fold, and intermediate dilutions. We now take up into our capillary pipette one volume of each of these dilutions, mixing in each case with one volume of the suspension of corpuscles. Holding at arm's length the capillary pipette which contains this series of mixtures and disposing the tube so that light may strike upon it obliquely we take cognisance of the hæmolytic effect. Opacity and a bright appearance, referable to the reflection of light to the eye, indicate incomplete transparency, and a dark colouration, due to the absence of reflection, indicate complete hæmolysis. Usually complete hæmolysis is obtained on mixing one volume of the $\frac{N}{50}$ (0·117 per cent.) or $\frac{N}{60}$ (circ. 0·1 per cent.) sodium chloride solution with one volume of the corpuscular suspension.

Precautions to be observed in collecting the serum and urine which are to be compared.—In each case the samples of blood and urine are obtained from patients who have not drunk anything for a period of hours. Where accurate comparisons are required the bladder is emptied before commencing operations. A sample of blood is thereupon withdrawn and as soon as possible afterwards a sample of newly secreted urine is passed.

Procedure for making the progressive dilutions of serum or, as the case may be, of the urine and for mixing these in each case with equal volumes of the standardised suspension of red corpuscles.—The technique to be employed is exactly the same as that employed in the standardisation of the corpuscular suspension. It is convenient in each case to begin with a 4-fold dilution and then to follow on with an 8-fold, 16-fold, and if necessary 32-fold dilution. When a dilution which gives complete hæmolysis has been arrived at we can, by going back upon the original 4 fold dilution, make for ourselves the particular intermediate dilution which may be required. This will be a 6-fold, 12-fold, or 24 fold dilution according as the complete hæmolytic effect has been obtained in an 8-fold, 16-fold, or, as the case may be, 32-fold dilution.

Usually in the case of the normal serum complete hæmolysis will be achieved with the 8 fold but not with the 6-fold dilution. In the case of the normal urine it will be achieved with either the 16-, 24-, or 32 fold dilution.

We obtain a convenient—but only approximately accurate—expression for the concentration of the serum or urine we are testing by setting it down as x-times greater than that of the salt solution which was in the standardisation of the corpuscular suspension found to effect complete hæmolysis—x representing in this expression the dilution of the serum or urine which had been arrived at when the complete hæmolytic effect was obtained. Adopting this system of notification the concentration of the serum and urine was found to be as follows in a series of normal men.

TABLE I.—*Setting forth the Concentration (expressed in terms of NaCl) of the Serum and Urine and the Excretory Quotient of Normal Adult Men.*

8	26/2/04	0·78	1·56	2

* The subject of these observations perspires a great deal and excretes proportionately less urine.

† The subject of this observation had drunk freely some hours before. In association with this it may be mentioned that the subject of observation Number 1 was successful in reducing the concentration of his urine to less than 0·1 per cent. NaCl by drinking 1500 cubic centimetres (circ. three pints) of water upon an empty stomach.

It will be seen that the concentration of the serum is a very constant function in health and that the excretory quotient is, if we except the first observation made in the case of the man denoted by the serial number 7, always two or more than two.

---

It is brought out in the cases tabulated above that the serum is modified in a characteristic way. The improvement which appears in the successive observations made in Cases 4, 6, and 7 may, perhaps, be referred to the treatment. It will be observed that the excretory quotient in the two cases where it was tested conforms to the normal.

Concluding remarks and question as to the precise significance of the method of testing here recommended.—We have seen above that the investigation of the *hæmolytic index*[2] of the serum or, as the case may be, the comparative estimation of the hæmolytic indices of the serum and urine is likely to prove of utility in connexion with clinical work. It may clear up a diagnosis, it may tell us whether a patient is in a condition to undergo a surgical operation, it may give warning of the approaching advent of uræmic symptoms, it may assist the physician in selecting the proper dietary for a patient who is suffering from Bright's disease, and it may [illegible] between so-called *functional* and organic [illegible] not essential to the achieve- [illegible] at the exact significance of the test should be cleared up it is obviously a desideratum that we should know so far as possible what it is that we are measuring. It seems probable that what is measured by the hæmolytic index is generally the salt content of the fluid. This is not the place to go into the consideration of the grounds upon which this inference is made. It will suffice to bring out the following The presence of urea in a fluid is, so far as this test is concerned, a matter of indifference, hæmolysis being obtained at precisely the same point when diluting with a 5 per cent. solution of urea as when diluting with distilled water. The specific electrical conductivity of the fluids which we have, by the kindness of Dr. A. D. Waller, been able to test in the physiological laboratory of the University of London was found to be roughly[3] proportional to the salt content of the fluids as estimated by the method here in question. This is exhibited in the table below (Table IV.).

---

[2] [illegible] index" is signified the fraction which [illegible] case may be of the urine, [illegible] when added in each case [illegible] pension of red corpuscles.

TABLE IV.

Fluid tested.	Relative concentrations of the fluids in salts as determined by the hæmolytic method.	Relative concentrations of the fluid in salts as determined by the specific electric conductivity.
Ascitic fluid from patient with acute nephritis	100	100
Urine from same case	75	89
Urine from case of parenchymatous nephritis	50	57
Urine from case of interstitial nephritis	50	40

In conclusion attention may be drawn to the fact that specific hæmolysins, such as are found in the blood of animals which have been immunised by injections of red blood corpuscles, do not come into consideration in connexion with the hæmolytic method as here applied. This is shown by the fact that the "hæmolytic index" of serum, or as the case may be of urine, which has been exposed to a temperature of 65° C. for ten minutes is exactly the same as that of the unheated serum or urine. Attention may be drawn also to the at present quite unexplained fact that the hæmolytic index of serum, or as the case may be of urine, which contains a considerable quantity of albumin, is represented by a higher fraction after it has been raised to the boiling point. It is to be noted that this alteration of the hæmolytic index is not associated with any comparable alteration in the specific electric conductivity of the fluid.

TABLE V.—*Setting forth the Dilutions with which a Complete Hæmolytic Effect was obtained in the case of Serum and Urine tested before and after Exposure to a Temperature of 100° C.*

Nature of fluid whose hæmolytic index was examined.	Hæmolytic index of the unheated fluid.	Hæmolytic index of fluid after exposure to a temperature of 100° C.
Serum from normal man	1-8th	1-16th
Serum from another normal man	1-8th	1-16th
Serum from patient suffering from amyloid disease of the kidney, &c.	1-8th	1-32nd
Serum from patient suffering from interstitial nephritis	1-8th	1-16th
Serum from patient suffering from parenchymatous nephritis...	1-16th	1-32nd
Serum from another patient suffering from parenchymatous nephritis	1-16th	1-32nd
Non-albuminous urine from normal man ...	1-32nd	1-32nd
Urine with trace of albumin derived from a patient suffering from cystitis due to infection by the bacillus coli	1-16th	1-16th
Urine with trace of albumin derived from a case of renal disease	1-32nd	1-32nd
Urine with trace of albumin derived from a case of renal disease	1-16th	1-16th
Highly albuminous urine from a case of renal disease	1-8th	1-32nd
Urine containing a considerable amount of albumin	1-5th	1-16th

---

[3] It will be manifest that in the case of the hæmolytic method we multiply our error of observation in each case by the factor which corresponds to the dilution we have arrived at.

VACCINATION EXPENDITURE.—At the meeting of the Penzance board of guardians held on March 25th it was decided to support the resolution passed by the Liskeard (Cornwall) board of guardians protesting against the greatly increased cost of carrying out the Vaccination Act and asking the Government to draw up a more economical system.

REMARKS ON THE RELATIONS OF PULMONARY TUBERCULOSIS TO OTHER DISEASES.[1]

BY F. PARKES WEBER, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GERMAN HOSPITAL AND TO THE MOUNT VERNON HOSPITAL, HAMPSTEAD.

PULMONARY tuberculosis is so widely disseminated that it is not surprising to find it occasionally associated with nearly every other disease. It is partly on this account no easy matter to decide whether a given disease has any causal relationship whatever to pulmonary tuberculosis. The following questions arise: Is one disease favourable or antagonistic to the onset or spread of the other, or is there some more indirect relationship between the two diseases—for instance, that a certain state of the body which is opposed to one of the diseases is likewise either opposed or favourable to the other, or lastly, is the association of the two diseases merely accidental? These questions are often exceedingly difficult to answer. Statistics are mostly meagre or untrustworthy and in many cases we are driven back to general impressions of the various observers on the subject. I shall not have time to consider tuberculosis of the lungs in all its associations with other diseases but must limit myself to the question of its relations to certain constitutional defects and to certain diseases of the heart, liver, and kidneys. I shall not discuss its relations to other diseases of the lungs and air passages.

Relations of pulmonary tuberculosis to diseases of the heart.—Louis and Rokitansky[2] held that there was an antagonism between heart diseases and phthisis, but Traube[3] thought that there was no antagonism between aortic reflux and phthisis, whilst Peacock,[4] Traube,[5] and nearly all modern authorities find[6] that patients with congenital pulmonary stenosis, if they live to an age of about from 15 to 20 years, frequently die from tuberculosis of the lungs. On the whole it seems that conditions of the circulation which tend to passive hyperæmia of the lungs (not merely increased venosity of blood) have a hindering action on the growth of tubercle, whilst anæmia of the lungs favours tuberculosis. Thus it is maintained that active pulmonary tuberculosis rarely arises in the subjects of mitral reflux or of mitral stenosis, and cases have been observed in which the signs of pulmonary tuberculosis became much less marked and the disease became decidedly less active after the development of rheumatic mitral disease. It is said that tubercle bacilli have been found in vegetations from endocarditis, but even if we grant that their presence has once or twice been demonstrated Teissier's paper[7] as to the tuberculous origin of cases of mitral stenosis does not carry conviction with it.[8] It may here be mentioned that some medical men, influenced by Bier's writings on his method of treating tuberculosis of the joints[9] by artificially induced hyperæmia, have advocated the adoption of certain positions of the body and certain local thermal methods as part of the treatment of pulmonary tuberculosis,[10] with the object of increasing the amount of blood in the vessels of the lungs. In regard to the association of congenital pulmonary stenosis with tuberculosis of the lungs it must be remembered that this may be attributed not only to defective supply of blood to the lungs but likewise to the general defective development of such patients, especially to a tendency to "infantilism" (see later section) Percy Kidd[13] says· "Such persons are born with imperfect lungs and it is not to be wondered at that these organs should be prone to so common a disease as tuberculosis '

Relations of pulmonary tuberculosis to diseases of the liver —*Amyloid disease of the liver* is well known as occasionally due to suppuration connected with tuberculous disease in various parts of the body, but it is really only a very rare complication of tuberculosis of the lungs and, owing to modern surgical and other methods of treatment, it is doubtless becoming a much less frequent complication of tuberculosis altogether, even of hip disease and spinal caries Enlargement of the liver from *fatty infiltration* is so frequently found in consumptive patients dying after prolonged hectic fever that a causal connexion between the two conditions is universally admitted Most probably the glandular cells of the liver become so damaged by the febrile condition, or, rather, by the toxæmic cause of the pyrexia, that their metabolic functions become seriously impaired Their feeble power of combustion is then shown by the accumulation of the fatty droplets I should here state that probably there is no sharp demarcation line between fatty infiltration and fatty degeneration of the liver ; the latter process is probably really a fatty infiltration in an atrophic liver when the hepatic cells have degenerated not only in functional power but in the amount of their living cell-substance also[13] *Cirrhosis of the liver* is not very rarely found associated with peritoneal or pulmonary tuberculosis or both, and there are good grounds for believing that in a few cases hepatic cirrhosis may be due to a local tuberculous process[13] In regard to the association of an ascitic form of tuberculous peritonitis with cirrhosis of the liver Dr S Gee[14] says· "Perhaps the tuberculous poison sets up cirrhosis, like alcohol, and one is reminded of a similar association of ovarian tumours with cirrhosis of the liver " There is, however, another and more generally acknowledged connexion between pulmonary tuberculosis and hepatic cirrhosis—namely, the fact that alcoholism may be a factor in the production of the pulmonary as of the hepatic disease Osler[15] writes "A remarkable feature is the association of acute tuberculosis with cirrhosis In seven cases of my series the patients died with either acute tuberculous peritonitis or acute tuberculous pleurisy Pitt states 22½ per cent of the cases of cirrhosis dying in Guy's Hospital during 12 years had acute tuberculosis Of 121 autopsies at the Manchester Royal Infirmary[16] in cirrhosis about 23 per cent gave evidence of tuberculous infection 12 of these had tuberculosis of the peritoneum and 12 died directly from the tuberculous infection " This naturally brings me to the following subject

Relations of pulmonary tuberculosis to alcoholism —Much has been written on the effects of alcohol in regard to consumption and there is still much difference of opinion as to the value of alcohol in the treatment of the disease Yet one can well understand that if alcohol in moderate doses increases the patient's appetite, favours digestion, and makes him more cheerful, it may, by promoting the general nutrition of the body, indirectly help to check the progress of the tuberculous disease On the other hand, abuse of alcohol, at least, chronic alcoholism, is now almost universally admitted to be a great predisposing cause of pulmonary tuberculosis. That this should be the case is not very surprising if one remembers how readily the subjects of chronic alcoholism fall victims to other diseases of microbic origin, such as acute pneumonia and septic inflammations Chronic alcoholism favours degenerative processes all over the body and diminishes the resistant power of the tissues to microbic infection The cells of the different parts of the body in alcoholism seem to become sluggish in regard to their metabolic functions so that the vital reactions of the tissues become less prompt and less efficient This supposition explains the tendency to accumulation of fat in the liver and subcutaneous tissues and explains why pyrexia is often less marked and why alcoholics succumb more readily than others on very prolonged exposure to cold Probably just as the tissues of alcoholics respond less readily than those of ordinary persons to demands for increased heat production, so in infective diseases their antitoxin forming and other microbe resisting powers are less efficient The bloated type of alcoholic—for instance, the old style of brewer's drayman—has always been notorious for extreme liability to wound infection and acute septic gangrene following injuries and in such a person one can imagine that not only have the anti microbic and antitoxin forming functions of the cells of his body been dulled by the habitual action of alcohol, but even that, owing to his "bloated" condition, the really living portions of his body—namely, the cells—are abnormally separated from each other and therefore less able to cope with the intruding microbes Be this as it may, French inquiries[17] into the subject as well as English observations[18] leave no doubt about the reality of the connexion between alcoholism and pulmonary tuberculosis Moreover, the children of alcoholics are often born with deficient resistant power and thus fall an easy prey to tuberculosis I must here state, however, that I believe it is going too far to regard alcoholism, as some writers on the subject have done, as the only connecting link between pulmonary tuberculosis on the one hand and peripheral neuritis and hepatic cirrhosis on the other Cirrhosis of the liver may occasionally, as I have already mentioned, be of local tuberculous origin and polyneuritis may in some cases be due as much to the pulmonary tuberculosis itself as to any associated alcoholism, but to this I shall return later

Relations of pulmonary tuberculosis to diseases of the kidneys —Typical amyloid disease of the kidneys (I do not here refer to slight amyloid changes accompanying parenchymatous nephritis) is occasionally met with in cases of pulmonary tuberculosis but I believe it to be exceedingly rare Parenchymatous nephritis[19] and forms of mixed parenchymatous and interstitial nephritis are, on the other hand, much more frequently found They occur especially in patients with advanced pulmonary tuberculosis and in these cases the kidney disease is, I have no doubt, usually a result of the lung disease, of which it constitutes a most serious complication I regard the nephritis in most of these cases as caused by irritation due to toxic substances absorbed into the circulation from the tuberculous and suppurating foci in the lungs, but it must be remembered that the nephritis may occasionally be associated with local tuberculosis and that the presence of tubercle bacilli has sometimes been detected in the kidneys, even in the absence of regular tubercles[20] Here I would mention that slight amyloid changes, easily to be detected by examining microscopic sections stained with methyl violet, frequently accompany the changes of chronic parenchymatous nephritis, both in the case of consumptive patients and others This is not surprising when one remembers the experience of N. P. Krawkow[21] and others regarding the artificial production of amyloid disease Krawkow seems to show that amyloid disease is usually the result of absorption into the blood of products of the metabolism of parasitic microbes, and he actually succeeded in inducing amyloid changes in the tissues of a rabbit by repeated injections of the mere filtrate of a culture of the bacillus pyocyaneus

Recurrent attacks of gout with typical chronic interstitial nephritis are relatively rarely[22] associated with pulmonary

[22] In regard however to the kidney disease without taking gout into consideration W H Dickinson (Diseases of the Kidney, London 1875 p 378) found tubercle in 20 8 per cent of 250 persons dying from granular degeneration of kidneys which according to statistics was less than the average frequency of tubercle in all post- [illegible] of Chronic [illegible] I made out [illegible] ears old with [illegible] died from [illegible] chronic inter [illegible] necropsies on

the liver and spleen. Tubercle bacilli were seen in specially stained sections of the liver and (what is much more remarkable) in the bone marrow from the shaft of the left humerus.

The association of lymphadenoma with tuberculosis has been repeatedly described in medical journals and has constituted a subject for discussion at medical societies. Some observers have gone so far as to suggest that all the cases in question are tuberculous—in fact, that lymphadenoma is a variety of glandular tuberculosis. In the discussion on Lymphadenoma in its Relation to Tuberculosis at the Pathological Society of London, in December, 1901, Dr. F. W. Andrewes[43] concluded that lymphadenoma is a distinct disease, not due to the action of the tubercle bacillus; that there is a form of tuberculosis of the lymphatic glands clinically indistinguishable from lymphadenoma; that a fair number of cases of lymphadenoma occur in which secondary infection with tubercle has taken place; and that this secondary infection may be local and unimportant, or the patient may die from generalised tuberculosis with a mixture of lesions of the most puzzling kind. It was such a mixture of lesions that the case to which I have just alluded showed. Cases of this kind should be separated from cases of multiple tuberculosis of lymphatic glands. There are doubtless, as Dr. Andrewes says, some cases of the latter class which cannot be distinguished clinically from lymphadenoma (Hodgkin's disease), but there are also cases which can be recognised during life (without "bioscopic" help, including exploratory operations, of any kind and without even the use of tuberculin), as examples of chronic multiple tuberculosis of lymphatic glands. They may be diagnosed (1) by there being no, or only very slight, enlargement of the spleen or liver; and (2) by there being evidence of associated pulmonary tuberculosis.[44] Such a case I have at present under observation at the German Hospital.

The patient, a married woman, aged 32 years, is a fairly "well-nourished" woman with a rather florid complexion. The lymphatic glands of each side of the neck and of the right axilla are enlarged. The inguinal glands are enlarged but not more so than they are in many healthy persons. The spleen and liver do not seem abnormally large. The patient first came under observation in October, 1903. She knew that the glands in the right axilla were affected two and a half years previously. But those in the neck had only been enlarged during the last six months. She had lost weight and presented physical signs of slight tuberculosis of one lung. The blood showed that there was no great anæmia: hæmoglobin, 90–95 per cent.; red cells 4,600,000, and white cells 12,000, per cubic millimetre. The urine was free from albumin and sugar. In the hospital her general condition has remained about the same.

Several cases have been published illustrating the association of tuberculosis with leukæmia (mostly cases of lymphatic leukæmia[45]). It has been observed that after tuberculous infection there are often retrogression in the size of the spleen and lymphatic glands and diminution in the number of the white cells in the blood; for this reason Professor H. Quincke of Kiel,[46] has even suggested the employment of tuberculin in leukæmia. Retrogression of leukæmic symptoms has also been observed as a result of erysipelas[47] and other microbic invasions. Susmann[48] suggests that the excess of nucleo-albumin and the increased phagocytic power of the blood in leukæmic patients may exercise an antagonistic action in regard to tubercle. It is not certain, however, that leukæmia is really antagonistic to tuberculosis, though tuberculosis seems to check the progress and even to cause retrogression of leukæmia.

The relations of pulmonary tuberculosis to diabetes mellitus.—Pulmonary tuberculosis is well known to attack not very rarely patients suffering from grave diabetes, and Sir Lauder Brunton[49] has suggested that the presence of sugar in the tissues facilitates the growth of microbes and renders diabetics peculiarly liable to certain bacterial affections, pulmonary tuberculosis amongst others. Though tuberculosis is a most unfavourable complication of diabetes a diminution in the sugar, or even its complete disappearance from the urine, is occasionally observed to follow the onset of the pulmonary disease. The cautious employment of tuberculin might, as far as I can see, be proposed for diabetes as it has been for leukæmia. And probably with as little likelihood of success, for one must remember that the diminished excretion of sugar in diabetics when they become consumptive may, as has been suggested, be due merely to the pyrexia or the mixed bacterial toxins causing pyrexia; moreover, disappearance or diminution of the sugar may be a temporary result of other microbic invasions, accompanied by pyrexia, besides tuberculosis.

The relations of pulmonary tuberculosis to syphilis.—A certain amount of antagonism between syphilis and tuberculosis has been supposed to exist by some medical observers, but many authorities, especially the majority of French writers, think that syphilis by lowering the general powers of resistance to disease predisposes persons to tuberculosis. It has even been suggested, I believe, that a reason why syphilitic gummata are so rarely seen in the lungs is that a counter-infection with tubercle bacilli generally occurs, so that a case of pulmonary syphilis is generally transformed into one of pulmonary tuberculosis.[50] Whether persons who have had syphilis are more easily, or less easily, infected with tubercle than persons who have never had syphilis is a question which for obvious reasons cannot easily be answered. It has been supposed by some that syphilis, like alcoholism, in the parents renders the children peculiarly liable to pulmonary tuberculosis.[51] I formerly repeatedly saw an intelligent man who was suffering from pulmonary tuberculosis, and also from fibrous stenosis of the larynx for which tracheotomy was performed. In 1899, when I first saw him, he was 41 years old, and had had a form of lupus verrucosus of the right hand for 18 years. He was dumb and almost completely deaf. The presence of pulmonary tuberculosis was made certain by a marked general reaction following the injection of half a milligramme of Koch's old tuberculin and afterwards by the discovery of tubercle bacilli in the sputum. Mr. R. Lake, who operated on the patient's larynx in the Mount Vernon Hospital, believed the great amount of old cicatricial tissue he met with to be of syphilitic origin and the supposition of congenital syphilis would probably account for both the laryngeal and aural conditions present. In spite of his unfavourable circumstances he seemed rather resistant to the progress of the tuberculous disease. He died at his own house, I heard, in February, 1903, but I am uncertain of the exact cause of his death.

The relations of pulmonary tuberculosis to multiple neuritis.—It is generally recognised that some causal relationship exists to account for the relatively frequent association of multiple neuritis of the alcoholic type with pulmonary tuberculosis. Dr. H. W. G. Mackenzie[52] says that it is almost invariable to find tubercle present in the lungs in patients dying in the course of alcoholic paralysis. The frequency of this association has been used as an argument to prove that alcoholism creates a predisposition to tuberculosis. It doubtless can do so, and I have already considered that subject, but it is no longer supposed as, I believe, it formerly was that any case of multiple neuritis affecting the lower extremities is necessarily due to alcohol. It is notorious that those most addicted to alcohol are not always the ones that suffer from neuritis. Given exciting cause or causes of polyneuritis it is evident that all persons are not equally affected by them, some being more liable than others (for instance, women more so than men). In those who are specially predisposed it is probable that tuberculosis (or rather a toxæmic condition arising from pulmonary consumption), like several other microbic diseases, may act as an exciting cause in association with alcohol or even independently.

TWO CASES OF "CORSET CANCER," WITH REMARKS ON THE ORIGIN AND SPREAD OF CANCER.[1]

BY R. CLEMENT LUCAS, M.B., B.S. LOND., F.R.C.S. ENG.,
SENIOR SURGEON AND LECTURER ON SURGERY AT GUY'S HOSPITAL; CONSULTING SURGEON TO THE EVELINA HOSPITAL FOR CHILDREN.

MUCH attention is now being directed to the origin and spread of cancer and, whilst a committee of investigation is at work to endeavour to track the disease to its initial causation, any new site of origin to which attention has not been directed may be of interest to the profession. I have therefore taken this opportunity of drawing attention to a mode of onset—I am almost inclined to say mode of entry—in the immediate neighbourhood of the breast which at first is not in the breast and only spreads to the breast secondarily or by extension contact. Three cases of this mode of origin have recently been under my care but the report of one of them has unfortunately been mislaid and I can only give the details of two.

The site where this carcinoma attacks the skin and cellular tissue is over an upper and outer radiant from the nipple corresponding exactly to the point where the upper edge of a corset crosses the edge of the pectoralis major muscle. It occurred on the right side in each case and in women whose occupations led them to an undue use of the

to an excessive friction of the

ver the edge of the pectoralis

ndicated. The friction of the corset at this spot is therefore the cause of the cancerous process developing in this situation and to express the fact I have given it the name of "corset cancer."

CASE 1.—The first case was that of a single woman, aged 47 years, who was admitted under my care in Guy's Hospital on Oct. 30th, 1901. Her parents were both living and healthy at an advanced age and previously to her admission her general health had been always good. She was a worker in a fur factory and her employment for years had been to scrape the fur of rabbits' skins with a blunt knife so as to draw out all the long hairs and to reduce them to a uniform low level, after which they were dyed to imitate seal-skins and other valuable furs. For many hours every day her arm was carried backwards and forwards in this work and her pectoral muscle moving to and fro whilst she leaned over her bench pressed the soft tissues injuriously against the upper edge of her corset. In March, 1900, the patient first noticed a hard swelling of about the size of a nut situated above, and to the outer side of, her right breast. It continued to grow, remaining hard and painless except when pinched or pressed upon. After a time she noticed that the pressure of the corset in her work caused her pain and she left off wearing it. A month before her admission the lump broke down and began to ulcerate. When admitted she had the appearance of a stout, plethoric, healthy, middle-aged woman. Above, and to the outer side of, the right breast close to the anterior fold of the axilla was a round raised ulcer about one and a half inches in diameter with a definite raised margin and a discharging surface. Underneath the ulcer could be felt a hard lump of about twice the diameter of the ulcer but freely moveable and in no way adherent to any deeper structure. The patient's appetite was good, the bowels were regular, and the temperature was normal. On the back of the patient's neck was a red serpiginous rash running in incomplete circles and curved lines and tending to desquamate. When seen by me on Nov. 1st it was diagnosed as a case of "corset cancer" but as the serpiginous eruption gave a suspicion of syphilis five grains of iodide of potassium were given every six hours. On the 9th the report stated that she had been ailing with loss of appetite and pains in her right arm, wrist, and hand, and also in the right thigh. On the 19th the pains in her joints had ceased and no effect had been produced on the ulcer by antisyphilitic remedies. It was therefore determined to remove the growth. A.C.E. mixture was administered and an elliptical incision in a transverse direction was made to include the growth. The incisions were carried through the edge of the breast and cellular tissue down to the pectoral muscle, the fascia of which was dissected up. From the centre of the upper incision another, three or four inches in length, was carried up into the axilla and the growth with glands and adipose tissue of the axilla were all dissected out together. During the operation some discharge escaped from the deeper parts of the growth and contaminated the wound. It was brought together with catgut and a gauze drain was introduced below. On the 25th some suppuration was noticed and the wound was thoroughly washed out with 1 in 500 of formalin and packed with cyanide gauze soaked in formalin. On the 30th the wound was cleaner and the temperature was normal. The patient was discharged on Dec. 22nd. A microscopic examination of the tumour showed the growth to be carcinomatous. On Oct. 27th, 1902, she was readmitted with a hard red growth over the upper aspect of the breast and two smaller ones, one being in the axilla. On the 30th an anæsthetic was administered and they were all separately excised. She was discharged on Nov. 24th. On Oct. 9th, 1903, she was readmitted with several secondary growths about the skin over her right breast. There were no growths in the axilla. The whole area affected, including the breast, was excised on Oct. 20th. A part of the wound was left to granulate. She made good progress and was sent to a convalescent home on Nov. 4th, 1903

CASE 2.—The second case was that of an unmarried woman, aged 59 years, who was admitted into Guy's Hospital under my care on Nov. 4th, 1903, for swelling and pain near the upper and outer edge of the right breast. She had been employed for 36 years in a laundry, carrying the iron backwards and forwards over the linen for many hours every day. In appearance she was a tall, rather slight, delicate woman. She had had pleurisy twice and on one occasion an abscess in her neck. On the outer side of the superior external quadrant of the right breast was a small hard tumour causing a distinct dimple in the skin. It corresponded exactly with the friction level of the upper edge of her corset as it crossed the margin of the pectoralis major muscle. The tumour formed a depression of about the size of a shilling by its firm adhesion to the skin but was freely moveable on the tissues beneath. The breast and the nipple below were normal. One small gland was to be felt in the axilla. On Nov. 10th an anæsthetic was administered and the tumour was excised. The incision was carried on into the axilla and the gland was excised. The tumour removed was proved to be a carcinoma by microscopic examination. She was convalescent at the end of a week and was discharged from the hospital on the 18th but unfortunately the small wound left became contaminated at her home and she was readmitted with suppuration and a high temperature on the 30th. The wound had to be opened up as well as an abscess which had formed in her gluteal region, after which she recovered.

I have placed these two cases together for comparison and it will be noted that they were both single women advanced in life who had worked hard to gain a livelihood by their

in pre-

and to

ent had herself noticed the injurious effect of the margin of the corset upon the spot where the tumour developed. The movement of the right arm to and fro in their work was again very similar in the two cases, the first woman having been employed for years in scraping the fur of rabbits' skins and the second for no less than 36 years in ironing in a laundry. To my mind, to use the phrase of a late distinguished politician, "there can be no shade of a shadow of a doubt" that the injurious friction of the margin of the corset for many years was the determining cause of the cancer developing at this particular site.

Local irritation and lowered vitality determine the site.—This is but a new illustration of a well-established fact that different forms of carcinoma are apt to attack parts the vitality of which has been lowered or the resistance of which has been lessened by chronic irritation, neglected ulceration, or cicatrisation. It was long ago pointed out that epithelioma was apt to commence on the edges of orifices where mucous membrane joined the skin and by a curious coincidence last October there were in my ward for males at the same time a case of rodent ulcer attacking the lower eyelid, a case of epithelioma of the lower lip, a case of epithelioma of the prepuce and glans penis, and one of the margin of the anus, cases forming an interesting group on which to found a clinical lecture. It is easy to surmise why the cancerous process favours these situations since the covering is there tender and at the same time more exposed to injury and infection than other parts of the body. The facts that cancer of the lower lip rarely occurs except in pipe smokers and that epithelioma of the prepuce is commonly associated with phimosis or else commences in the scar of an old chancre give further support to the same view. Paget's eczema of the nipple preceding cancer of the breast and chimney-sweep's cancer attacking the scrotum, where the large sebaceous glands have long been choked with soot, are both well-recognised incidents in causation.

---

[1] A paper read before the Brixton Medical Society on March 17th, 1904

Relation of syphilis to cancer.—I should like now to point out how frequently syphilis is the forerunner of cancer in various situations where it leaves its injurious effects, and possibly one of the many causes contributing to the increase of cancer is the unchecked distribution of this disease. I have already alluded to epithelioma attacking the sites of old chancres on the penis. In two cases of amputation of the penis for cancer that I have performed within the last few months the patients declared that the growth commenced in the scars of old chancres. Next the chronic glossitis of the tongue, which commences with the secondary stage of syphilis and is kept up by smoking and by foul, irregular, and decayed teeth, is the most frequent precursor of epithelioma of the tongue. I hold it most important advice to insist on patients giving up smoking during the treatment of the secondary stage of syphilis, lest this affection should run on into that incurable stage of white scarring and thickened epithelioma, which has been described under many names, such as leucoplakia, psoriasis, and ichthyosis, and for which in the advanced stage, being struck by the resemblance it presents to the *appearance of a parrot's tongue*, I suggested many years ago the term "psittacosis." Epithelioma may attack the cheek, tonsil, palate, and larynx long after the ulceration due to syphilis in these situations has healed. Epithelioma of the tongue, which is so common in men as compared with women, is probably in the main attributable to these two causes—syphilis and smoking. In all my professional experience I have only once removed a tongue from a woman for epithelioma and in this case there was a distinct syphilitic history. She had been infected with syphilis on marriage about 15 years before and had suffered from recurrent ulceration of the tongue ever since, followed by leucoplakia. At the time I operated upon her she had an epitheliomatous ulcer of the tongue and enlarged glands in the neck which I removed at the same time. I have met with three cases in which cancer of the rectum followed syphilitic stricture of this part of the bowel; two of these were in women and one was in a man. In the latter case I operated on the syphilitic stricture when it had contracted as a cicatricial valve, so small that it did not admit the tip of one's forefinger, by incising and then dilating with large bougies. The patient was told to keep the stricture dilated by passing a bougie twice a week. About three years later he began to suffer from blood and slime with his motions and on re examining him I found a new growth in the circumference of the bowel. I performed a colotomy and he lived for three years after, but eventually the growth penetrated the os innominatum and formed a large tumour at the junction of the left loin and buttock and he gradually sank.

Inoculation, contagion, and infection.—I now come to the question of contagion and infection in relation to cancer and I am inclined to think that if special investigation were directed to this subject it would not be difficult to arrange some very important facts in support of these modes of origin. In THE LANCET of Oct. 8th, 1887, p. 727, the following paragraph appeared: "M. Duplouy of Rochefort reports a case where a man, who had for a long time carefully nursed his wife, who was suffering from uterine cancer, became affected with epithelioma of the glans penis, necessitating amputation. The question arises, Is this a mere coincidence, or does it point to the possibility of a cancer being transmitted by contagion?" A few weeks later Mr. T. G. Laslett[2] wrote: "In 1883 a man was admitted into the Liverpool Infirmary suffering from epithelioma of the penis. He stated that his wife had died some time before of cancer of the womb and he though this complaint was something which he had contracted from her." Dr. E. Hooper May[3] also wrote: 1883 a patient of mine, aged 53, died with cancer of uterus and I have since been informed that in 1886 husband, aged 57, had to submit to amputation of the for cancer, of which complaint he died a few months Since that time I have operated on one case of epitheli of the penis in a man who stated that his wife from cancer of the womb some time before his dis commenced.

These cases present a strong probability of contagio inoculation where the circumstances are peculiarly fav able for such a mode of transmission. Against conta it has been urged that cancer cannot be inoculate the lower animals from man and, though this appears t true, recent observations clearly show that cancer occu in the lower animals can with great certainty be inocul into another animal of the same species. In 1889 Har finding a rat suffering from cancer, was the first to prove the disease could be conveyed by inoculation to other Moran[5] in 1894 conveyed the disease from a cance mouse to other mice. Jensen[6] of Copenhagen has made hundreds of transmissions of cancer from mice to mice, these observations have been confirmed in this country recently by Dr. E. F. Bashford and Dr. J. A. Murray.[7] tumours sent over sterile from Copenhagen were used five days after posting and reproduced the disease in According to these observers the cells inoculated grow the tumours produced arise from the actual cells introd without any participation of the cells of the host. Bo of the Pasteur Institute has gone further and has shown the disease may be conveyed by natural means. He pl two cancerous mice in a cage with several sound ones an a result found that five or six of the latter became cance In the human subject there are often seen cases of metas by transplantation or self-inoculation where one sur affected with cancer has been allowed to rub against a s surface. I have several times seen patches of epitheli on the inside of the cheek immediately opposite to, independent of, a cancer of the jaw or tongue prod apparently by inoculation. But the most striking case this kind are one by Williams[9] of cancer of the t spreading to the opposite thigh and one by Cripps of ca of the skin of the arm caused by contact with an ulcera cancer of the breast.

It would follow from these observations that canc transmissible by direct inoculation from one part cancerous person to another part, that it is inoculabl animals of the same species from one suffering from can and that sound animals mixed with cancerous animals of same species may in this way acquire cancer. It se highly probable therefore that it is in some degree inoculable and contagious among human beings. leads me to speak of infection or transmission am persons living under the same roof and under similar ditions.

Cancer houses.—I think my own observation of t persons living together in the same house was the firs direct attention to cancer spreading in this way which D'Arcy Power[10] has done much to elaborate since. observation was published in THE LANCET of Nov. 1 1887, p. 985, in a letter under the title, "Is Cancer tagious?" I then wrote as follows: "The following cur instance of three different forms of cancer, occurring in t individuals living together in the same house may some receive an explanation other than that of mere coincide In 1881 and again in 1883 I operated on a gentleman su ing from rodent ulcer of the eyelid and forehead. H still living but with a return of the growth. In 188 operated on his wife for scirrhus of the breast and du the past week a partner who has always lived in the s house with them, has come under my care with epitheli of the tongue. I would *not suggest that there is* necessity anything more than accidental association betw these cases, but the coincidence is the more interestin that there is no blood relationship between them." three forms of cancer here alluded to are all of the squa epithelial variety and therefore not widely separated structure and may be conceived to be produced by the same exciting cause modified by the tissue inoculated.' Since that time I have met with a good many cases in which two cases of cancer have occurred in the same house.

Resemblances in cells of malignant growths to those of reproductive tissues.—Within the last six months much interest has been elicited by a paper showing that changes which take place in the nuclei of cancer cells undergoing multiplication exactly resemble the changes which take place in the ripening of reproductive cells. This paper was read before the Royal Society on Dec. 10th, 1903,[11] and the observations were confirmed by Dr. Bashford and Dr. Murray in a paper before the same society read on Jan. 21st, 1904.[12] To make this clear I may mention that "chromosomes" is the term applied to rod-like bodies within the nuclei which stain with aniline dyes. These have been closely studied by von Hansemann (1893) who found the amount of chromatin to vary and to express which he used the terms "hyperchromatosis" and "hypochromatosis" in relation to the cells of malignant growths. But the value of the work of Professor Farmer, Mr. Moore, and Mr. Walker lies in the demonstration that the central cells of all cancer growths entering into mitosis have the number of chromosomes reduced to just half the normal number, whilst the form of the chromosomes is changed from an elongated thread-like V-shaped chromosome to a short ring-like form. This reduction to half the number of chromosomes is precisely what is observed in the reproductive cells of both plants and animals undergoing mitosis, and has led the observers to conclude that malignant growths are virtually reproductive tissue occurring in abnormal situations. Whilst this power of reproduction illustrates the manner in which cancer growths rapidly increase in size it does not to my mind explain in any way why particular cells of any organ of the body should start this heterotype mitosis in imitation of the normal reproductive cells. Moreover, the value of this observation as an explanation of cancer causation is much weakened by the fact that the same kind of cell division with reduced number of chromosomes is observed in sarcomata—tumours which clinically as well as microscopically are widely separated from true carcinomata. I am inclined, therefore, to regard this valuable new observation as serving to demonstrate to us the manner in which the cells of sarcomata and carcinomata so rapidly multiply by imitating the processes normal to the reproductive cells, but beyond this there must lie a cause which compels them to take on this exceptional process. That cause still remains to be demonstrated.

To sum up the points of this short paper: 1. I have demonstrated a site of origin of cancer dependent upon the friction of the upper edge of a corset where it crosses the anterior fold of the axilla. To this I have so far attached no theory save that of chronic irritation, but supposing cancer to be due to an organism introduced from without, the rubbing in of such organism at this spot might aptly be compared to the rubbing in of staphylococci on the back of the neck by the collar in the production of boils and carbuncles. 2. Allusion was next made to other recognised sites of origin associated with irritation and especially to the points of junction of mucous membrane with skin. 3. I then attempted to show how syphilis, producing injurious effects in numerous situations, often proved to be the forerunner of cancer. 4. Next inoculation and contagion were considered; the proved inoculability of cancer in animals of the same species; the self-inoculation in the human subject of parts in contact but not continuous; and the probable communication of the disease in certain cases from wife to husband. 5. The infection of cancer was then spoken of and my original observation of three persons having cancer at the same time in the same house, published in 1887, was quoted. 6. The recent observations of Professor Farmer, Mr. Moore, and Mr. Walker as to the resemblance of the mitotic changes of cancer cells to those normal in the reproductive cells of plants and animals were alluded to as of great interest, showing why in both cancers and sarcomata there exists such an immense power of multiplication of cells, but why the cells assume this heterotype mitosis still *remains to be demonstrated.*

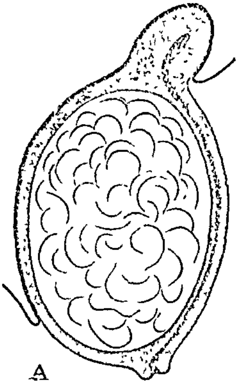
A TOPOGRAPHICAL AND CLINICAL STUDY OF FIBROIDS OF THE NECK OF THE UTERUS (CERVIX FIBROIDS).

BY J. BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN AND ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

IN May, 1897, I exhibited at the *Obstetrical Society* of London some large specimens of fibroids growing in the neck of the uterus and drew attention to the fact that tumours of this kind had not received adequate attention at the hands of those who had given close attention to the surgery of the uterus. These tumours are by no means rare, they possess very characteristic features, and sometimes offer formidable difficulties when submitted to operation. In order to obtain some notion of their relative frequency I carefully analysed 500 cases of fibroids which have been under my care for operative treatment during the past eight years and find that in every 100 cases there will be five in which the fibroids occupy the cervix, and of these five, three, and sometimes four, will be fibroids exceeding the dimensions of a fist; in the early stages of growth cervical, like the common forms of uterine, fibroids are more or less globular, but when they exceed this size tend to become ovoid. Fibroids may grow from any part of the cervix; commonly they arise from its walls in such a way as to occupy the cervical canal (Fig. 1). These are known as intracervical or submucous cervical fibroids. Less frequently they grow from the periphery of the cervix and do not invade the canal but burrow under the peritoneum on the anterior or the posterior aspect of the uterus (Figs. 2 and 3). These are known as subserous cervical fibroids.

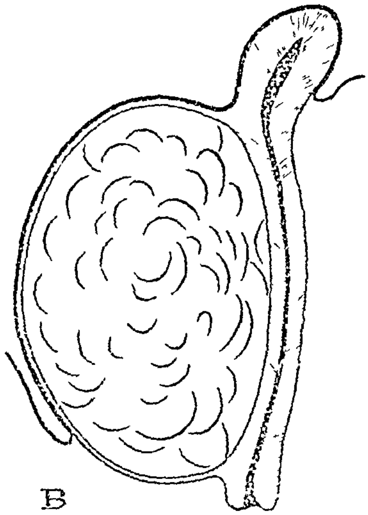
FIG. 1.



A diagram to show the relation of an intracervical fibroid to the cervical canal.

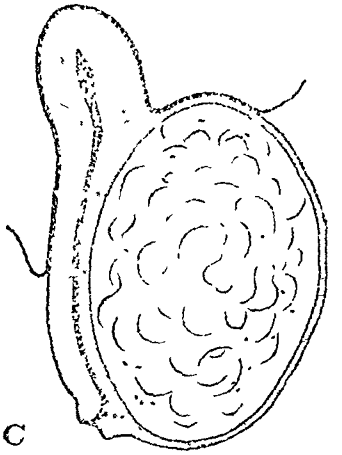
The oval character of the cervical fibroid is best displayed in the submucous variety, for as it grows it pushes the body of the uterus, which is perched on its upper pole, high into the abdomen and in the case of very large tumours the fundus of the uterus can be detected as high as the navel. The topography and shape of this kind of tumour are best displayed when they are sectioned in a sagittal direction. The ovoid sha[illegible] the osseous bounda[illegible] male pelvis the pelvic [illegible] the cervix measure, with the soft parts in position, about ten centimetres (four inches); thus the lower segment of a large cervix fibroid is a solid cast of the true pelvis. In one of my specimens the minor (transverse) axis of the tumour measured 12·5 centimetres, this excessive measurement being due to the slow but steady expanding effects of the tumour on the bony walls of the pelvis. It is well to bear in mind that the oval condition of the vaginal pole of a large cervix fibroid corresponds with the shape of the occiput of a recently delivered fœtus at term. The ovoid shape is also attained by subserous cervical fibroids when they grow from the posterior aspect of the cervix as shown in Fig. 2. This kind of tumour as it increases in size pushes the body of the uterus high out of the pelvis on its upper pole, but its relation to the cervical canal is worth some attention. The intracervical fibroid, as shown in Fig. 1, uniformly expands the cervix, and in very large specimens its tissues form a thin covering to the tumour; but a fibroid of the posterior aspect of the cervix elongates it without expanding the canal and is really situated between the cervix and the peritoneum. This is a topographical distinction of some importance in connexion with the clinical aspect of these tumours.

Fig. 2.



A diagram of a fibroid growing from the posterior wall of the cervix, showing its relation to the peritoneum.

Fig. 3.



A diagram of a fibroid growing from the anterior wall of the cervix to show its relation to the peritoneum as it passes from the anterior wall of the uterus to the bladder.

Fibroids on the anterior aspect of the neck of the uterus remain more or less globular and do not distort the shape of the cervix as a rule; when of large dimensions they push their way upwards between the peritoneum and the anterior abdominal wall; in one example under my care the whole of a large tumour of this kind had become extraperitoneal. It is a noteworthy feature of the cervical fibroid that in more than two-thirds of the cases the tumour is solitary. All varieties of cervix fibroids are furnished with a distinct capsule; the tumour tissue on section presents the characteristic whorled arrangement of the common form of uterine fibroid and is microscopically identical with it. Fibroids of the neck of the uterus when they do not cause menorrhagia are very insidious and rarely give rise to serious symptoms until large enough to fill the pelvis and to exert pressure on the urethra, the vesical segments of the ureters, and the rectum. In some cases, especially variety C (Fig. 3), there is direct pressure on the bladder. The frequency of micturition, dysuria, and retention of urine, which are such frequent concomitants of the varieties A and B, are due to the bladder being dragged upwards by the uterus as this organ is pushed out of the pelvis by the growing tumour.

I am induced to prepare this paper with the hope of reconciling some divergent opinions as to the frequency or otherwise of menorrhagia in connexion with cervical fibroids. With this object in view I analysed the clinical reports of 20 cases under my care in the Chelsea Hospital for Women and the Middlesex Hospital. I have appended brief notes of ten consecutive cases in which two points come out very clearly: (1) menorrhagia and metrorrhagia are only noticed with the intracervical variety and bear no relation to the size of the tumour; and (2) hæmorrhages (menorrhagia and metrorrhagia) only occur with intracervical fibroids when the uterus has made attempts to extrude, or has succeeded in extruding, the tumour wholly or partially into the vagina. The corollary is plain. An extruded or partially extruded fibroid is exceedingly liable to become septic and as surely as this happens menorrhagia and metrorrhagia are unfailing consequences.

Case 1.—The patient was a single woman, aged 41 years. She had a large intracervical fibroid. There were profuse metrorrhagia and profound anæmia. The os uteri was widely open. Panhysterectomy was performed on Dec. 14th, 1899. (Chelsea Hospital for Women.)

Case 2 —The patient was a single woman, aged 45 years. She had a very large intracervical fibroid. The os uteri was a mere dimple. Menstruation was normal. She complained of pelvic pressure and retention of urine. Panhysterectomy was performed on May 7th, 1900. (Chelsea Hospital for Women.)

Case 3.—The patient was a single woman, aged 45 years. She had a large fibroid growing from the posterior aspect of the supravaginal cervix. There were menorrhagia and dysuria. Panhysterectomy was performed on Sept. 9th, 1901. (Chelsea Hospital for Women.)

Case 4 —The patient was a married woman, aged 52 years, who had had six children. She had a large intracervical fibroid. The os uteri was patulous. There was profuse and prolonged menstruation. Panhysterectomy was performed on Oct. 21st, 1901. (Chelsea Hospital for Women.)

Case 5.—The patient was an unmarried woman, aged 38 years. She had a large intracervical fibroid pushing the uterus high out of the pelvis. Menstruation was scanty but regular. There was frequent micturition. The os uteri appeared as a dimple at the lower pole of the tumour. Abdominal enucleation and supravaginal hysterectomy were performed on Jan. 27th, 1902. (Middlesex Hospital.)

Case 6 —The patient was a married woman, aged 36 years She had had four children. A large fibroid was growing from the anterior aspect of the supravaginal cervix. There had been amenorrhœa for three months. She had frequent micturition. Abdominal enucleation of the tumour was performed on May 12th, 1902. She was delivered of a boy at full term on Jan. 2nd, 1903. (Chelsea Hospital for Women.)

Case 7.—The patient was a married woman, aged 49 years, who had had two children. She had an intracervical fibroid. There was dysuria. Menstruation was irregular. There was painful pressure on the rectum. Panhysterectomy was performed on March 17th, 1902. (Chelsea Hospital for Women.)

Case 8.—The patient was a married woman, aged 45 years, who had had six children. There was a very large fibroid growing from the anterior aspect of the cervix and extending upwards beyond the umbilicus. The tumour is described in the notes "as big as a football." Menstruation was irregular but not profuse. Supravaginal hysterectomy was performed on Sept. 10th, 1902. (Middlesex Hospital.)

Case 9 —The patient was a married woman, aged 43 years. She had had one child and one miscarriage. She had an extruded intracervical fibroid of the size of a turkey's egg. There was profuse metrorrhagia. Vaginal myomectomy was performed on Nov. 10th, 1902. (Chelsea Hospital for Women.)

CASE 10.—The patient was a married woman, aged 31 years. She was sterile. She had a fibroid of the size of a turkey's egg growing from the anterior wall of the cervix and pressing on the bladder. This filled up the vagina, hindering coitus. Vaginal enucleation was performed on May 18th, 1903. (Chelsea Hospital for Women.)

The largest intracervical fibroid known to me is a specimen (Hunterian) preserved in the Museum of the Royal College of Surgeons of England. It measures 30 centimetres (12 inches) in length by 12·5 centimetres (five inches) in width. Unfortunately it is without history.

A close study of these ten cases brings out some further facts. It will be noticed that in some of them the condition of the mouth of the womb is described in this way: "The os uteri was a mere dimple"; wherever this sentence appears it almost certainly follows that menstruation is described as normal, scanty, or irregular and a closer study of the records shows that the patient is usually a spinster or, if married, sterile. On the other hand, the great majority of the women in whom the intracervical fibroid is a source of menorrhagia have borne children and present a patulous and often widely patulous os uteri. It should also be borne in mind that cervical fibroids of all varieties, though commonly solitary tumours, are occasionally complicated by a submucous fibroid in the body of the uterus and this is, of course, a notorious agent in producing metrorrhagia.

A glance at the brief notes of the ten cases shows that these cervix fibroids do not lend themselves to any routine kind of operation. When of moderate size and associated with a capacious vagina the intracervical kind and those which arise on the anterior aspect of the supravaginal cervix may be easily, expeditiously, and safely enucleated through this channel. Tumours which attain and exceed the bulk of a fœtal head at term almost invariably demand treatment by the abdominal route. I have tried a variety of methods. When the uterus with the tumour in its cervix can be raised out of the pelvis far enough to allow the necessary manipulations then panhysterectomy can be performed easily and quickly. Occasionally the tumour is wide and so fixed in the pelvis that it will be necessary to split the uterus longitudinally and to enucleate the fibroid from its bed; then an ordinary supravaginal hysterectomy can be carried out. The enucleation of a large impacted cervix fibroid requires to be conducted carefully without undue display of force or so much shock is produced that the patient's life will be placed in the gravest peril. However, large cervix fibroids can be safely enucleated even when the uterus is gravid, as Case 6 testifies.

Perhaps the acme of difficulty is that met with when the body of the uterus is occupied by a large fibroid and another, even larger, grows from the posterior aspect of the cervix and tightly blocks the pelvis. In this particular condition the fibroid can be enucleated from the cavity of the uterus; the larger tumour is then shelled out of the pelvis and the uterus is removed as in an ordinary supravaginal hysterectomy. The lower extremity of the capsule forms a pouch and the unexpanded vaginal portion of the cervix lies in its anterior wall; before suturing the stump in order to secure free drainage into the vagina I split the cervix longitudinally with scissors. In one instance in which I divided the uterus longitudinally in order to extract a large, tightly impacted intracervical fibroid, instead of removing the uterus I sutured the two halves and left the organ intact. The patient recovered without even a rise of temperature. In conclusion, there is no form of uterine fibroid likely to test the judgment, resources, and common sense of the surgeon to such a degree as a large cervix fibroid tightly incarcerated in the pelvis. The three diagrams used to illustrate this article were drawn by my colleague Dr. A. E. Giles who has assisted me in the removal of many difficult cervix fibroids.

Brook-street, W.

ERRATUM.—In the paper by Dr. Alexander Marmorek on Treatment with Antituberculous Serum, published in our last issue, the words "in which tubercle bacilli were found" (see THE LANCET, March 26th, p. 859, column 1, line 6) were deleted by the author and printed by us in error.

A CASE OF SLOUGHING OF THE CENTRAL PART OF A UTERINE FIBRO-MYOMA SHORTLY AFTER DELIVERY.[1]

BY JOHN D. MALCOLM, F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE following case is interesting on account of the fact that an acutely formed slough was surrounded by living healthy fibro-myomatous new growth and also because a fibro-myoma touching the mucous membrane and the peritoneum was removed by enucleation without serious hæmorrhage.

The patient's age was 32 years. She married in March, 1902, and miscarried in September of the same year. On Oct. 25th, 1903, she had a still-born child of about seven months' gestation. Her medical attendant was not present but he delivered the placenta an hour later. Much blood was lost for five hours after delivery and many clots were passed during the following four days. On the fifth day the vaginal discharge was very offensive, the patient's temperature was high, and she felt very ill. She gradually got better and the discharge ceased but much pain in the pelvis continued. Her medical man told her that this was caused by a tumour attached to the womb which had been there since her delivery and which would probably get all right. He ceased to attend after about four weeks. The pain increased very much as the patient tried to move about and on Dec. 10th she sent for another practitioner, with whom I saw her seven weeks after delivery, and she was admitted to the Samaritan Free Hospital on the next day. She had then a mass in the pelvis, apparently between four and five inches in diameter, closely attached to the womb, which lay to the right and behind. The swelling was always painful but the slightest manipulation and every movement caused intense suffering. The uterine cavity measured just over two and a half inches in length and there was no vaginal discharge. The temperature was 99·4° F. on admission to hospital but on the next day it was normal and it did not again rise until after the operation. Except for the presence of the mass attached to the uterus and some anæmia the patient seemed to be quite healthy. I thought that possibly there might be an extra-uterine fœtation but a diagnosis of inflamed fibro-myoma seemed to explain the conditions better.

On Dec. 18th, 1903, the fifty-fourth day after delivery, as there was no improvement, the abdomen was opened and a tumour which was obviously a uterine fibroid was exposed. The most prominent part seemed to be covered by little, if anything, but peritoneum and the uterus which was well involuted was attached to the back and right side of the growth. The body of the uterus could be seen and felt standing well out from the growth and they seemed to be slightly mobile on each other. The appearances suggested that the tumour was not very deeply buried in the wall of the uterus and it was therefore decided to attempt to remove the fibroma and to leave the uterus. An incision was made through the capsule and enucleation was effected without much difficulty. Only one vessel bled sufficiently to require a ligature, all other hæmorrhages being controlled by sponge pressure. The tumour was placed, however, much more deeply than I thought, and in removing it the cavity of the uterus was laid freely open. A sound passed through the cervix made this quite certain. Nevertheless, hæmorrhage was unimportant and I therefore closed the wound in the uterine wall. The deeper parts were brought together by a continuous catgut suture, but it was impossible to adjust the mucous surfaces accurately and drainage into the uterine cavity was therefore free. The outer walls of the capsule which had contained the tumour were then inverted, but to do so it was necessary to shorten them considerably. This had the advantage of making their edges much thicker and there was no difficulty in inserting Czerny-Lembert sutures so that no part of the silk entered the cavity from which the tumour was removed. The necessary shortening of these flaps caused very little bleeding. Two small pedunculate fibroids of about the size of marbles were also removed from the back of the uterus and no other tumour was detected. The patient made an uninterrupted recovery, there being a considerable vaginal discharge for the first few days.

---

[1] A paper read before the Obstetrical Society of London on Jan. 3rd, 1904.

The tumour appeared to be an ordinary fibroid and showed no sign of degeneration until it was incised. Then it was seen that about half an inch all round had the appearance of an ordinary living fibro-myoma, whilst the central part was a whitish-grey slough. There was no possibility of separating the central from the outer part except by using a knife. There was no odour. After being in spirit a few days the colour had all gone, but it was obvious that the external part had contracted more than the central. The appearance was very similar to that shown when a fibroid in the uterine wall has been incised and kept in spirit, but in such a case it is normal uterine tissue that retracts. Mr. W. Sampson Handley kindly made a section of the growth, including part of the central sloughed tissue and part of the unaltered tissue. The surrounding growth stained well with eosin and hæmatoxylin and showed numerous muscular cells with well-stained nuclei. The sloughed part took on little stain and showed hardly any structure, no nuclei being visible. It was apparently in a state of mucoid degeneration. There was a definite line of demarcation between the well-stained and the slightly-stained parts.

These conditions are unique in my experience. It does not seem that there was an ordinary sloughing due to septic influences absorbed from the uterine cavity. The growth was so close to the mucous membrane that contamination from this source must inevitably have induced a putrid slough of the whole tumour, and the death of the patient would probably have followed, because the growth was as near to the peritoneal as to the mucous surface.

The greater contractility of the outer portion of the growth suggested that the central part was more fibroid and less vascular, but probably the difference was due to a degeneration of the sloughed tissue. Nevertheless, the large number of muscular cells must have subjected the central part of the growth to considerable pressure, and this, together with the diminution of the vascular supply caused by the involution of the uterus, seems to afford the most satisfactory explanation of the sloughing of the central part of the growth. According to this view the slough was aseptic and it is probable that if the patient had been kept absolutely quiet sufficiently long the dead tissues would have been very slowly absorbed.

The advantages of enucleating the tumours and of leaving the uterus in a recently married woman, 32 years of age, are obvious. But it should not be forgotten that the surgical completeness of the operation, whilst it gives the patient the opportunity of becoming a mother, exposes her at the same time to the risks involved in the presence of a long scar in the uterine wall, and this condition must give rise to considerable anxiety if the patient should become pregnant again.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF TETANUS TREATED WITH ANTITETANIC SERUM; RECOVERY.

(Under the care of Dr. J. ROSE BRADFORD.)

FOR the notes of the case we are indebted to Mr. W. F Annand, house physician.

The patient, a well-nourished, healthy-looking woman, aged 70 years, was admitted into University College Hospital on Nov. 25th, 1903, at 2 P.M., said to be suffering from tetanus. The history was that on Nov. 22nd she began to feel cramp-like pains in her right leg, which during the next two days spread to the abdomen and thence up the spine. On the 24th she was said to have had a typical tetanic spasm. Ten cubic centimetres of antitetanic serum were injected beneath the skin of the abdomen and the patient was sent to the hospital. On admission a large healing ulcer was present on the front of the right leg, measuring six inches by three inches. Its base was firmly fixed to the bone. No other breach of the surface was discoverable anywhere. The temperature was 97·8° F., the pulse was 96, and the respirations were 24 to the minute. There were slight rigidity of the jaw muscles, slight difficulty in swallowing, and inability to protrude the tongue beyond the teeth. There were no other signs of importance. At 4.30 P.M. the patient had an attack of violent spasm. There were intense pain in all the muscles, along the spine particularly, and marked opisthotonos, the body being bent like a bow, resting only on the occiput and the heels. The eyebrows were screwed up, the angles of the mouth were drawn, and the jaws were firmly clenched. The thorax was absolutely fixed and respiration was entirely suspended. The spasm lasted for about a minute and then passed off, leaving the patient very cyanosed and for a short time unconscious. This condition passed away in two or three minutes. From 4.30 P.M. on the 25th to 12.30 P.M. on the 26th there were 11 attacks of spasm at fairly regular intervals, the third, fourth, and fifth being very slight. An enema of 30 grains of chloral had been given after the first attack and another was given after the last. At 2 P.M. on the 26th chloroform was administered, the ulcer was excised and the surface left was scrubbed with peroxide of hydrogen. An injection of 100 cubic centimetres of antitetanic serum was made beneath the skin of the abdomen. On coming round from the anæsthetic two very severe spasms occurred at 6 and 6 45 P.M. The pulse showed signs of failure and brandy was given frequently. She slept well during the night. At 3 P.M. on the 27th a further injection of 90 cubic centimetres of serum was made near the site of the former injection, this time without an anæsthetic. At 4 o'clock there was a severe spasm, resembling in all respects those which had occurred before. Until Dec. 1st the history was uneventful, no further attacks occurring. On that date the temperature rose for the first time, reaching at night 99·8°. During the evening the patient complained of considerable irritation over the front of the abdomen, the lower part of the back, the knees, and the wrists. There was present on examination an urticarial erythematous eruption consisting of minute white papules on a ground of vivid pink. There were slight headache and nausea for from eight to ten hours. On the following day the rash was general. On the afternoon of the 4th the temperature began to rise steadily, reaching 101·8° on the night of the 5th. There was considerable pain in the wrist-joints, the metacarpo-phalangeal joints of the thumbs, and the interphalangeal joints. They were all swollen and excessively tender, the skin over them being red and glossy. On the 5th there was slight laryngitis, with hoarseness and cough. The knee-joints were swollen and fluid was detected in each. By the 7th the rash and the arthritis were lessening and these had gone by the 10th. The temperature continued going up and down until the 14th, the highest rise occurring on the 8th, when the thermometer registered 102·6°. During this time, on the evenings of the 9th and 10th, two syncopal attacks occurred. Another attack occurred on the 14th, when the patient became unconscious, the chest was fixed, and respiration stopped. This lasted a few seconds and then the back arched as in the tetanic spasms at the beginning of the illness. No special measures were taken. From this time onward convalescence progressed uninterruptedly. On the 23rd a Thiersch graft was applied to the ulcer which united perfectly. The patient was discharged well on Jan. 23rd, 1904. Unfortunately the piece of tissue forming the floor of the ulcer which had been excised was lost and no microscopical or other examination was made of it.

Remarks by MR. ANNAND.—The case seems to me to be interesting as showing the result of the large injections of antitetanic serum now recommended. The patient had in all 200 cubic centimetres of serum subcutaneously; the rash appeared on the seventh day from the time of the first injection of 10 cubic centimetres and on the fifth day from the date of injection of the first large dose of 100 cubic centimetres. The arthritis appeared on the tenth or eighth day, according to whether one reckons from the date of the small or large injection. That the successful issue of the case is due to the use of the serum, which was supplied by the Lister Institute of Preventive Medicine, is, I think, indubitable.

MONTAGU COTTAGE HOSPITAL, MEXBOROUGH.

A CASE OF PYLORIC STENOSIS AND GASTRIC DILATATION OF VERY LONG DURATION (21 YEARS); POSTERIOR GASTRO-ENTEROSTOMY; COMPLETE RECOVERY.

(*Under the care of* Mr. B. CROSSFIELD STEVENS.)

THE patient was a man, aged 40 years. He was thin, emaciated, and bedridden, and unable to retain food or to digest it. He stated that his illness dated from the age of 18 years, when a horse rolled on him. Pain in the stomach and vomiting came on soon afterwards and three months later he went to the Sheffield Infirmary, where he was put to bed, kept on a milk diet, and had his stomach washed out. He still vomited and had pain a few hours after food. After three months as an in-patient he was made an out-patient and continued to attend for three years and was able to work occasionally. Ten years previously, still suffering from the same symptoms, he went to the Sheffield Royal Hospital and after five weeks' lavage, dieting, and rest was discharged. From that time up to two months previously, when first seen by Mr. Stevens, he had been treated privately. When Mr. Stevens saw him the emaciation was extreme; the man was unable to take anything without pain accompanied by vomiting, proximate or remote, and was going downhill fast. The friends were very adverse to any surgical procedure until they understood that it was operation or a lingering death. Under carbonic acid gas distension the stomach was quite two inches below the umbilicus. The pylorus could not be felt but most of the pain was at the cardiac end. Succussion splash was easily obtained and was very pronounced. The vomit was acid and frothy; it was never tinged with blood.

Owing to the weak condition of the patient he was given 20 minims of liquor strychninæ hypodermically and a saline enema with brandy and the operation was completed within three-quarters of an hour. The pylorus was a hard gristly mass but gave no indications of being malignant nor were there any adhesions to the gall-bladder or any viscus. The stomach having been washed out a few hours before was empty and large. The ordinary method of posterior gastro-enterostomy was done as Mr. Stevens had seen no vomiting usually after this route. The transverse mesocolon was opened, the stomach was pulled through and clamped, and the jejunum was looped up and ligated with rubber tubing. The anastomosis was made over a bone bobbin to act as a temporary splint for the surfaces to join over. Celluloid thread was used for the serous sutures and catgut for the mucous ones.

The patient was rather collapsed on return to bed. Liquor strychninæ and brandy were given every four hours. Hot water and plasmon were given by the mouth. A little pain and distension were present on the second day and this was relieved by the flatus tube. After this the patient never had a bad symptom; the pulse always kept below 100. The temperature was normal. There was never any hiccough or sickness. Six weeks after the operation the patient was well and walking about and was enjoying his food and had gained weight considerably. Great credit is due to the matron and the nurses for their assiduous attention.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

The Treatment of Urinary Tuberculosis.

A MEETING of this society was held on March 28th, Dr. F. DE HAVILLAND HALL, the President, being in the chair.

Mr. E. HURRY FENWICK read a paper on the Treatment of Early Urinary Tuberculosis. He advocated the use of Koch's new tuberculin in cases where the mucous membrane of the bladder was alone affected by the disease. He had used this remedy since its introduction in 1896 and found that in many instances it afforded real relief to the pain in the lower urinary passages. No claim for cure was advanced. It must not be used unless the tubercle bacilli were found in the urine by a competent observer. Its exhibition had to be carefully watched, for it was liable to light up trouble in one or other kidney latently affected by tuberculosis. In a large number of cases of urinary tuberculosis the cystoscope enabled the clinician to decide as to whether the kidney was affected or not, for the chronic form of the disease was almost always unilateral and the kidney was implicated early in the course of the disorder. When the kidney was shown by the cystoscope to have a ureter condensed and choked by peri-ureteritis he advocated its removal. He gave a list of 25 nephrectomies for tuberculosis with one death. Four of the female cases in this list became pregnant subsequently to the nephrectomy, two being delivered of healthy children. This afforded evidence that a single kidney in a tuberculous patient could bear the stress of pregnancy. Mr. Fenwick considered that the heavy death-rate of nephrectomy for tubercle of the kidney, just as that for carcinoma of the kidney, depended upon the surgeon not operating early, and he contended that the cystoscope would enable earlier interference and more judicious after-treatment. Should the cystoscope show a *single* ulcer in the bladder (and that condition was a rare one) he advised that it should be cut away suprapubically instead of using tuberculin. The same lines were employed in the male affected by genito-urinary tuberculosis. The affected testis or testes, vasa and seminal vesicles must be sacrificed if any good was to be effected. Should, however, the deposits be many and widespread, or should the history of tuberculosis of parts other than the genito urinary tract be obtainable, operation and tuberculin were useless and the best that could be done consisted in hygienic, dietetic, and therapeutic measures.

Dr. A. E. WRIGHT said that he had been engaged on work on somewhat similar lines. The use that had been made with the new tuberculin was not great. The new tuberculin consisted of the protoplasm of the tubercle bacilli and

"vaccine" against tuberculos

against plague and, as he had

against streptococcic infection. The new tuberculin could be used with success in those cases in which the tubercle was local and he had used it in such cases with a fair measure of success. He had inoculated a considerable number of cases and from the examination of the blood he had been enabled to construct a curve showing the increase of immunity. He had, however, only treated one case of urinary tuberculosis but in that case very marked improvement had taken place. He thought that it was only by an examination of the blood that a true estimate of the effect produced by the inoculation could be obtained. After the first inoculation a negative phase was produced which after two or three days became a positive phase. The positive phase gradually fell away and then it was that a fresh inoculation should take place. Immunity was in this way built up and he had treated several of the severer forms of tuberculosis in this manner with success.

Mr. F. SWINFORD EDWARDS said that tuberculosis of the urinary passages was one of the most distressing affections. He had treated a considerable number of such cases with Koch's new tuberculin and in all of them the symptoms were much relieved and three cases might be said to have been cured. This form of treatment marked a great advance. He had never knowingly tried it in tuberculous disease of the kidney. He thought that it might be of value in diagnosis as it gave rise to pain in the affected kidney. He asked why Mr. Fenwick did not recommend it in single ulcer of the bladder.

Mr. J. G. PARDOE said that he was quite certain that tuberculin injections were not only useless but actually harmful in advanced disease of the kidney. He had used it in six cases with unsatisfactory results. He asked whether it was possible to distinguish between an ascending or a descending tuberculosis of the ureter by the nature of the local affection of the bladder in the neighbourhood of the ureter. He said that a solitary tuberculous ulcer was most frequently situated on the trigone of the bladder and that it would be difficult to remove it from this situation.

Mr. J. W. THOMSON WALKER said that he had treated some eight cases of tubercle of the bladder by inoculation and had had three cases under observation for from three to ten months. In only one of these cases was there no improvement while in all the rest there was very marked improvement. The inoculation also tended to diminish hæmorrhage. In three cases of kidney tubercle and in one of ascending tubercle of the ureter no improvement had taken place. In two cases of early primary tubercle of the kidney no improvement had taken place in one, whilst marked improvement had occurred in the other. Tuberculin inoculation was not likely to do any good in the late cases of tubercle of the kidney but it was most beneficial in tubercle of the bladder.

The PRESIDENT asked whether a moderate degree of pulmonary tuberculosis negatived the use of this tuberculin. He also asked whether any special diet had been used and whether any drugs such as urotropin had been given at the same time as the injection.

Mr. FENWICK, in reply, said that when the urinary passages were affected with tubercle the lungs were very seldom affected and when there was pulmonary tubercle the urinary passages were seldom affected except in the late stages of the disease. He had not treated single ulcer of the bladder with tuberculin injection because he thought that it was best treated by removal. He was quite unable to distinguish between an ascending and a descending tubercle by the appearance of the bladder in the neighbourhood of the ureter but when he found that the ureter was retracted then he was certain that the kidney was affected.

CLINICAL SOCIETY OF LONDON.

Intestinal Obstruction immediately following Typhoid Fever.—A Case of Severe and Fatal Hæmaturia of Unknown Origin.—A Case of Attempted Division of the Eighth Nerve within the Skull for the Relief of Tinnitus.

A MEETING of this society was held on March 25th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. E W. GOODALL communicated a paper upon two cases of Intestinal Obstruction immediately following an attack of Typhoid Fever. The first case was that of a boy, 14 years of age, who was admitted to the Eastern Hospital at the end of an attack of typhoid fever, during the latter part of which there had been some abdominal pain. A relapse followed and at the end of this the patient suffered for three days from vomiting, hiccough, and pain in the abdomen. About three weeks later a second relapse took place, which was again followed by an attack of pain, hiccough, and vomiting. During this attack the patient died. At the necropsy the small intestine was found partly to be obstructed about two and a half feet above the valve by a fibrous band stretching from the mesentery to another part of the small intestine. Apparently this band had arisen out of a patch of local peritonitis opposite a deep ulcer. There were many healing ulcers in the small intestines. The second case was that of a young man, 22 years of age, who was operated upon for perforation on the twentieth day of an attack of typhoid fever. At that time there was no generalised peritonitis nor were there any peritoneal bands. The patient did well for about a fortnight when he began to suffer from vomiting. A week later there were other symptoms of partial obstruction and he died somewhat suddenly from a second perforation. At the necropsy a number of small bands were found kinking and compressing various parts of the small intestine. The second perforation was situated about six feet above the valve in an ulcer just above the highest band.—Dr. SEYMOUR TAYLOR inquired if there had been anything in the diet to account for the relapse, as he believed that such an event could frequently be traced to a change of food. As a sequela of enteric fever intestinal obstruction was so rare that most classical treatises were silent upon the subject. —Dr. GOODALL, in reply, said that he did not consider that a relapse in typhoid fever was necessarily associated with a change in the diet. The clinical history and post-mortem appearances of these cases suggested that the bands were formed out of local patches of peritonitis opposite intestinal ulcers.

Mr. WALTER G. SPENCER read notes of a case of Severe and Fatal Hæmaturia of Unknown Origin. The patient was a man, aged 44 years, who had first noticed blood in his urine about a fortnight before his death. His previous health was good. The chief symptom had been an increasing hæmaturia unaccompanied by pain or frequency of micturition. On admission to the Westminster Hospital he was very anæmic, practically pulseless, and dyspnœic. The bladder was distended but was not tense or tender. The temperature was subnormal. He was infused with salt solution, given repeated enemata of water, and stimulated with alcohol and strychnine. He passed urine containing a large proportion of blood and he died within 12 hours of admission. The post-mortem examination failed to throw any light on the cause or source of the hæmorrhage. The urinary tract appeared normal and no gross lesions were observed. The blood vessels were not diseased. Microscopical sections of the kidney, the vesical wall, and the aorta did not show anything abnormal, except that the wall of the latter vessel was perhaps thinner than was usual at this age. A second case of recurrent hæmaturia was also narrated in a man, aged 42 years, in whom the condition was temporarily arrested by suprapubic cystotomy and drainage of the bladder. Cases of hæmaturia unaccompanied by lesions had been referred to by Osler who mentioned Gull's term "renal epistaxis." Klemperer, in discussing this subject, used the term "angioneurosis." Some of the cases might be compared to those of post-operative hæmatemesis, where no gastric lesions were found.—Dr. W. P. HERRINGHAM remarked that in some cases of fatal hæmaturia varicose veins might be seen in the ureter. He thought that much stress could not be laid upon the size of the aortic coats as these were subject to great variation. A vascular origin of the condition was rather suggested by the age of the patients.—Dr. A. E. RUSSELL pointed out the analogy between certain cases of hæmaturia and those of fatal hæmatemesis and referred to a case of the latter affection in which a minute ulcer was found post mortem at the junction of several large vessels.—Dr. WILFRED HARRIS inquired if the coagulation time of the blood had been tested and also whether calcium chloride had been administered.—Mr. C. H FAGGE asked if there were any hæmoglobinuria present in either of the cases.—Mr. GEORGE EASTES inquired if the blood clots had been subjected to careful washing in water with a view to determining their origin by their shape when floated out.—Mr. SPENCER replied.

Mr. CUTHBERT S. WALLACE and Mr. H. J. MARRIAGE described a case in which an attempt had been made to divide the Eighth Nerve within the Skull for the Relief of Tinnitus. The patient was a female, aged 23 years, who developed left otitis media in 1898. Several operations followed and four years afterwards she began to suffer from tinnitus and vertigo, which symptoms increased in intensity to such an extent that her life was rendered thereby well-nigh intolerable. It was therefore decided to attempt to divide the eighth nerve. Numerous experiments were made on the cadaver with the result that a modification of the operation for the exploration of the posterior surface of the petrous bone was finally adopted and this was practised on Sept. 3rd, 1903. The operation was made very difficult on account of the constant discharge of cerebro-spinal fluid and also by the hæmorrhage from the surface of the cerebellum. The eighth nerve was exposed and divided by traction with a blunt hook. Noises were present on the following day. There was no facial paralysis. The wound never showed any reaction and continued to discharge. The patient gradually sank and died on the twenty-first day. At the necropsy it was found that a fine strand of the auditory nerve had escaped division. There was no meningitis and the internal ear presented a normal appearance.—Dr. E. FARQUHAR BUZZARD, who had made a microscopical examination of the nerve after staining by Marchi's method, said that the whole of the vestibular and two-thirds of the cochlear nerves were degenerated as a result of the section. He believed that very little was known with regard to the morbid anatomy of tinnitus, which was not a common symptom in gross organic disease of the brain except where there were lesions affecting the nerve roots at the base. The evidence that it was of central origin was not supported by pathological observation.—Mr. FAGGE referred to two cases in which he had exposed the eighth nerve and he had not found it a matter of great difficulty. He considered that tinnitus was more frequent after mastoid operations than was generally supposed and that it was probably of peripheral origin.—Dr. F. PARKES WEBER mentioned a case recorded by Alt of Vienna in which a leukæmic infiltration of the auditory nerve had been discovered in Ménière's disease, tinnitus being a prominent symptom in that affection.—Mr. WALLACE replied.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on March 18th, Dr. B. A. Whitelegge, the President, being in the chair.—Dr. H. T. Bulstrode, in the absence of the author, read a paper on the Epidemiology of Enteric Fever and Cholera in Hamburg by Dr. Reincke, medical officer of health of the city and port. The paper was illustrated by maps and diagrams. Hamburg, said the writer, with the adjacent but independent municipalities of Altona and Wandsbek, had a population of more than a million and extended for many miles along the right bank of the Elbe. It was originally built on the "geest," a deposit of the drift which skirted the whole coast from Schleswig to Holland, rising to a height of from 100 to 150 feet as a plateau above the "marsh" or low-lying alluvial beds between it and the sea or estuary, formed by the mud brought down by the rivers. With the exigencies of increasing commerce building had been extended over the marsh and on the "polders" or islands in the estuary, having been rendered possible by driving piles and the construction of dykes and embankments. A larger dyke, the Wetterung, ran parallel with the river, with houses on one side and market gardens and dairy farms on the other. Enteric fever was endemic in the villages of the marsh and probably many cases were caused in the towns by vegetables and milk infected by water from the Wetterung, that of the wells on the "geest" being charged with too much iron for domestic use. Prior to 1830 there was neither sewerage nor public water-supply in Hamburg, but the former was introduced in 1831 and the latter in 1842. The water of the river, however, was still used, as well as polluted, by the enormous floating population of barges, tugs, &c., and above all of the large river craft from the canals connecting the Vistula and Oder with the Elbe, 800 of which were often in the port at a time. The population of Hamburg, which in 1842 was only 160,000, was now 740,000, that of Altona 168,000, and of Wandsbeck 30,000. Each had its own waterworks, Hamburg taking its water from some miles above the town, Altona from below, though it was carefully filtered, but Wandsbek from upland lakes in Holstein. The course of epidemics of enteric fever in Hamburg and Altona was characteristic of the differences in their water-supplies, that of Altona being very much more exposed to pollution at its intake, but, save on some exceptional occasions, far more effectually filtered. Enteric fever in Hamburg showed a gradual curve extending over six months at least, whereas epidemics when they did occur in Altona through some breakdown in the filtering processes exhibited the features of an explosion, rising and declining rapidly within a much shorter period. The lighter incidence in Altona in ordinary years might be partly due to the lesser density of the population, but the sharpness of the line of demarcation was suggestive of its connexion with the distribution of the water-supplies. These accidents were more frequent formerly when the management of the filter-beds during continued hard frosts was less understood than it was now, and since 1893 no serious epidemic had occurred in either town. The number of cases had not of late exceeded 3 or 4 per 1000 population—i.e., from 200 to 300 per annum with about 30 deaths. Some were introduced by foreign shipping and many more by the barges engaged in inland navigation; but whether the residuum had any connexion with the water-supply would be certainly known only when the whole should be derived from deep wells as it would be before many years, though several towns with such supplies had as much enteric fever as Hamburg. The relation between the enteric fever and the movements of the ground water was obscure, as was the cause of the great rise of the curves in 1857, 1865, and 1889, and, in fact, when the level of the ground water was lowest. The same relation was observed at Munich, though there experience showed the absence of any connexion between the fever and the water-supply as clearly as the contrary was at Hamburg, and it was certain that since the improvement in water-supply and sewage disposal at Hamburg the fluctuations of the ground water had exerted no influence. Epidemics of cholera had been spread in like manner; introduced from Russia by the river craft it had followed the course of the inland water-ways except on the last occasion in 1892 when it came by sea from Paris and Havre. Then the influence of the water was conspicuously marked, the cases in Hamburg being 26·42 and the deaths 13·44 per 1000, those in Altona 3·81 and 2·13, and in Wandsbek 3·06 and 2·09, many of those in Altona and Wandsbek having been infected in Hamburg. This epidemic was explosive, attacking the whole city whether on marsh or "geest" simultaneously. Enteric fever had always broken out in epidemic form at the same time as cholera, beginning so much later only as its incubation period exceeded that of cholera, and this was but natural considering how dependent they both were on like conditions of soil and water. A form of choleraic diarrhœa had prevailed at the same time among infants but there had been a decrease of 1000 or 2000 deaths from this cause annually since the great improvement in the sanitary conditions of the town.—Mr. Shirley F. Murphy observed that the paper showed the large part played by water in the spread of the fever which we were apt to under-rate, and though in our milder climate the dangers of frozen filter-beds were less the experience of Altona proved the risks incidental to the use of sewage-polluted water, however carefully filtered. The reduction in the mortality from infantile diarrhœa following improved water service was remarkable, for we did not in this country commonly include water among the causes.—Dr. E. C. Seaton did not think that much enteric fever in this country was due to the use of river water, and though we had had outbreaks, as at Maidstone, owing to pollution of springs there was more typhoid fever in Liverpool and Glasgow with the purest mountain sources than in Hamburg and Altona.—Dr. A. Newsholme compared the cases of Munich and Hamburg, remarking that whatever influence rainfall and ground water might have exerted on the prevalence of enteric fever in former years it ceased to be traceable when the mortality had been reduced by improved sewerage and water-supply. Food and personal infection, especially by unrecognised cases, were more potent. The choleraic diarrhœa of Reincke was quite different from infantile diarrhœa or enteritis and was not unknown here in like association.—Dr. H. Franklin Parsons would on no account extenuate the influence of water, though with more deep wells and better filtration it caused fewer cases than formerly. We had in recent years had water epidemics at Maidstone, Lynn, Gloucester, and other places.—Lieutenant-Colonel R. H. Firth, R.A.M.C., observed that though the close analogy of the relations of cholera and of enteric fever with the water-supply had been amply proved in India we had been able to make no such impression on the latter as we had on the former.—Dr. E. W. Goodall understood that in Holland there was more enteric fever among those who drank from wells than among those who used the water of the canals, which Dr. E. F. Willoughby suggested might be due to the absence of sewers and the pollution of the shallow wells.—Dr. C. Childs remarked that the paper brought out clearly the influence of water in the spread of cholera and the value of efficient filtration. Altona with much fouler water *enjoyed comparative immunity*, thanks to its excellent filtration, which emphasised the terrible effects of a breakdown in the filters. The ground water of Hamburg was dependent on the rainfall and that at Munich on the depth and volume of the river. Pettenkofer began by holding the English view of water-supplies but found that no improvement in this direction had any influence on the prevalence or incidence of the disease, that being often heaviest where the water was the purest, and he deduced his theory from accurate and exhaustive observations.—Colonel J. Lane Notter, R.A.M.C., maintained that in South Africa water played a very small part, the main factors being flies, dust, soiled blankets, and personal infection among young men, dirty, overcrowded, and ill-fed.—After some remarks by Dr. Reginald A. Farrar the President summarised the salient points of the paper.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Liverpool on March 25th, Dr. W. J. Sinclair (Manchester), the President, being in the chair.—Dr. D. Lloyd Roberts (Manchester) related a case of Epithelioma of the Clitoris. The disease began in the glans and not, as is usual, in the prepuce which in this instance could be freely separated from the glans. Stress was laid on the early and persistent occurrence of intolerable itching and smarting in these cases and on the late appearance of pain. Dr. Lloyd Roberts had only seen three cases of the disease and the age of the patients was always over 50 years.—Dr. H. Briggs (Liverpool) remarked on the rarity of the condition as compared with the frequency of cancer of the penis.—The President said that despite its infrequency the condition was usually seen in an early stage but its treatment was unsatisfactory as speedy recurrence usually took place.—Dr. Nathan Raw (Liverpool) read notes of three cases of Ruptured Tubal Pregnancy which had come under his care in hospital recently. In two of the cases the onset was sudden and alarming, the patient becoming rapidly collapsed and semi-conscious, with all the symptoms of serious internal hæmorrhage. In the third case the onset was mild in its symptoms and the hæmorrhage was limited and not progressive, but in the course of ten days bleeding recurred with most alarming symptoms of collapse. In all three cases the abdomen was opened and found to be full of fluid and clotted blood. The ruptured tubes were ligatured and removed, recovery following in two cases; the third patient died two days after from shock. Dr. Raw strongly advocated early operation in all cases where the hæmorrhage was serious and progressive, although in a few cases it was desirable to wait a few hours until the patient had rallied from the state of collapse.—Dr. Briggs could not realise the meaning of the expression "an abdomen full of blood." He had never seen it and felt that hurried operations were a mistake. He had never operated upon a patient who was in a state of collapse, although it was easy to be persuaded that the patient was dying.—Dr. W. Blair Bell (Liverpool) thought that collapse should be treated by transfusion which was a somewhat neglected method of treatment. Probably the transfusion of four or five pints, together with some adrenalin, would allow of operation being performed in an hour's time.—Dr. Lloyd Roberts held that operation should be carried out as soon as possible after rupture had occurred. When there were signs of severe loss of blood it was impossible to tell whether the bleeding was persisting or not, therefore it was safer to open the abdomen.—Mr. R. Favell (Sheffield) suggested that implantation of the ovum in the isthmus of the tube might account for the severe bleeding in Dr. Raw's case.—Dr. A. Donald (Manchester) said that his experience of ruptured tubal pregnancy amounted to four cases and he considered that many cases of so-called rupture were instances of tubal abortion or tubal mole formation. If the tube had undoubtedly ruptured operation should be performed at once. It was possible that the bleeding might cease if the patient became profoundly collapsed but as soon as she rallied the hæmorrhage would recommence.—Dr. Arnold W. W. Lea (Manchester) had had four cases in which the tube was actually bleeding when the abdomen was opened. As a preliminary measure in such cases he had found benefit from placing a heavy sandbag over the abdomen to diminish the amount of blood passing along the abdominal aorta until preparations for operation were completed. He thought it ought to be possible to make an exact diagnosis as to the continuance or arrest of bleeding.—Dr. W. Walter (Manchester) took Dr. Donald's view. A bleeding vessel in the tube ought to be treated on ordinary surgical principles. The difficulty was to know whether the hæmorrhage was progressing. A history of previous collapses was in favour of a waiting policy but even in such circumstances the responsibility was very great.—Dr. J. E. Gemmell (Liverpool) thought that the symptoms in tubal abortion were due rather to peritoneal irritation than to loss of blood and considered that these two conditions could be differentiated.—Dr. J. M. O. Given (Liverpool) appealed from the general practitioner's point of view for some guidance on this somewhat bewildering matter.—The President remarked that in these cases the difficulties were not apparent to him. He had repeatedly seen the abdomen full of blood and sometimes actually distended by it.—Dr. T. B. Grimsdale (Liverpool) having spoken, Dr. Raw replied.

LIVERPOOL MEDICAL INSTITUTION.—A pathological meeting of this society was held on March 24th, Dr. James Barr, the President, being in the chair.—Mr. C. G. Lee and Mr. E. M. Stockdale showed three specimens of Endothelioma of the Retina. Mr. Stockdale remarked that these tumours were usually known as gliomata. One section showed tubules made up of a layer of conical cells, supposed to resemble the cones of the retina. This was considered to be an appearance noted in early specimens and the tubules were regarded as capillaries with modified walls. Other specimens showed blood-vessels surrounded by a sheath of new growth. In structure, therefore, these tumours resembled what was known under the name of plexiform angio-sarcoma, plexiform sarcoma, and cylindroma. Another specimen showed spaces filled with colloid material surrounded by cells.—Mr. D. Douglas-Crawford exhibited: (1) Section of Urachus; (2) an Excised Osteo arthritic Knee-joint removed for Excessive Hydrops Articuli; and (3) the Lateral Lobes of a Hypertrophied Prostate removed from a patient, aged 72 years.—Dr. K. A. Grossmann demonstrated a case of Removal of an Orbital Tumour of fibromatous nature and of slow growth. After two partial removals evisceration was finally necessary. There was no recurrence in four and a half years.—Mr. G. P. Newbolt showed: 1. A Large Multiple Villous Papilloma removed by suprapubic operation from a patient aged 55 years. Although the growth was very large symptoms had only existed for a year. 2. A Sacculated Bladder, the two parts being connected by an aperture only large enough to admit a probe. The patient was admitted with stricture of the urethra and pneumonia.—Concretions in the Appendix were shown by Mr. F. T. Paul and also by Mr. W. Thelwall Thomas. Mr. Paul was convinced that the immediate cause of appendicitis was almost invariably a mechanical irritant. Mr. Thomas gave some statistics collected by him which showed that concretions were not very commonly found. He mentioned that the duration of illness in his case was only 36 hours and that it was the first attack and would undoubtedly have ended fatally but for operative interference. —Dr. Kelly exhibited an excellent section of Psammoma and Dr. J. W. W. Stephens showed slides of the Leishman-Donovan parasite.—Mr. Keith W. Monsarrat exhibited the Gut from a case of Strangulated Hernia and Dr. A. S. F. Grünbaum showed specimens of New Growth from animals.—Dr. R. J. M. Buchanan read a note on a fatal case of Carbon Monoxide Poisoning from Coal Gas to which carburetted water gas had been added. The chemical and spectroscopic examination showed the characteristic features of CO hæmoglobin. The stomach was also shown and though six weeks had elapsed since death it retained the peculiar cherry red colour and showed no signs of putrefaction. The blood from another fatal case which occurred six years ago was also shown and had retained its peculiar colour and gave the characteristic reactions. Dr. Buchanan considered that gas companies manufacturing water gas should be required to notify the consumer when this was supplied.—Dr. Grünbaum gave a Spectroscopic Demonstration to show that the addition of potassium ferri-cyanide to blood saturated with coal gas altered the absorption bands to one broad indefinite band in the green. This change did not occur with blood saturated with pure carbon monoxide. The essential constituent of coal gas which formed this combination had not yet been determined. —Dr. W. Gordon Little gave a short account of the Purin Bodies and their Metabolism; he demonstrated Walker Hall's purinometer and stated that he found ammonium fluoride to be a better precipitant of uric acid than ammonium chloride, as used in Hopkins's method. He was engaged in observations with the object of finding a quick and trustworthy method of clinically estimating uric acid.

HUNTERIAN SOCIETY.—A meeting of this society was held on March 23rd, Dr. F. J. Smith, the President, being in the chair.—Dr. Paul C. Franze read a paper on the Physiological Action of the Nauheim Springs and the indications for their use chiefly in circulatory disorders. Dr. Franze explained that there were three springs containing chlorides of sodium, lithium, and calcium and carbonic acid gas in various proportions and having temperatures of 85°, 90°, and 95° F. The quantity of carbonic acid was further artificially regulated so as to produce (*a*) thermal baths, (*b*) thermal sprudel baths, and (*c*) effervescing or sprudel baths. The physiological actions of these baths were as follows:—1. An increased metabolism when they were employed colder than body heat. 2. A contraction of the vessels of the skin followed by reaction and dilatation—the well-known glow of the cold water bather—were produced in the Nauheim baths at temperatures only a degree or two below body temperature and with so little violence as to be suitable to cases of debilitated heart. This effect Dr. Franze chiefly attributed to the bubbles of gas stimulating the cutaneous nerves but he thought that in part it might be due to the local action of the salts on the capillaries of the skin. 3. This improved circulation led to a more active metabolism and this to a better and more active digestion and nutrition, whilst the tone of the nervous system was simultaneously improved. Dr. Franze claimed that low blood pressures were raised by the bath and that high blood pressures were lowered by it. The baths also relieved a heart which was too heavily loaded by peripheral spasm and filled an empty heart from the peripheral vessels. In fact, these baths afforded a means of administering the most delicately graduated exercises to the heart and circulation and therefore the cases suitable for the Nauheim baths were any cardiac cases which were not of so severe a degree that baths of any sort would be dangerous. If the patients could bear the journey safely they could bear the treatment. Valvular lesions, simple muscular weakness due to influenza, enteric fever or acute rheumatism, fatty hearts, and even arterio sclerosis with angina pectoris were greatly improved by a graduated course of baths.—Dr. Arthur T. Davies thanked the lecturer and said that he thought too much had been made at Nauheim of the reduction in size of the heart by a bath or two. The heart varied in size from minute to minute.—Dr. Alexander Morison was of opinion that cases of angina pectoris were unsuited for bath treatment.—Dr. T. Glover Lyon thought the benefit of Nauheim arose from its atmospheric depression which discouraged undue exercise.—Dr. E. H. Colbeck said he attributed the benefit of the baths rather to the mechanical action of the water, heat and bubbles than to any chemical action, either direct or indirect, of the chlorides.—Dr. L. A Smith, Dr. Bryant, Mr. H. L. Barnard, and the President also spoke.—Dr. Franze then replied.—A hearty vote of thanks was accorded to the lecturer.

GLASGOW NORTHERN MEDICAL SOCIETY.—A meeting of this society was held on March 22nd, Mr. C. F. Spinks being in the chair.—Dr. James Erskine read a paper on the Hospital History of Glasgow. The ancient hospitals, he said, were ecclesiastical. These old hospitals were placed outside cities, not for isolation, but for the reception of wayfarers. The oldest hospital related to Glasgow was one at Polmadie, called the Hospital of St. John, and was referred to in the year 1316, when Robert Bruce granted it a charter giving it all the privileges which it enjoyed in the time of Alexander III. Later it became a prebend to the Cathedral. St. Nicholas Hospital was founded in 1460 by Bishop Muirhead, probably to take the place of the Polmadie Hospital. The Barony Church now occupied the greater part of the ground of the old St. Nicholas Hospital which at that time housed 12 old men and a priest. Other hospitals were the Back Almons Hous, which accommodated four poor men, and those of the merchants and craftsmen. The Crafts Hospital adjoined the Hospital of St. Nicholas and lodged at first five, and later 13, freemen. Blackader's Hospital, near the Stable Green, was founded about 1524. It was situated where Dobbie's Loan joined Castle-street. It was for the reception of wayfarers and was described as "a house of the poor and indigent casually coming thereto." A hospital also existed at Strathbungo in pre-Reformation times. With regard to hospitals for the sick, a leper hospital was founded in 1350 on the south side of the Clyde, near the Stockwell bridge, but probably not, as was commonly stated, by Lady Lochow. This hospital disappeared about 1760. In the year 1645 wooden huts were erected in Sighthill to accommodate plague patients, the disease being then so prevalent that the University had to remove to Paisley for a time. The town's hospital was erected in 1733 by public subscription and was situated on the Old Green, near the Clyde. The Royal Infirmary was built in 1794 and John Burns was the first resident surgeon and apothecary. It was enlarged in 1816; the fever house was added in 1829 and the surgical house in 1861. The directors of the town's hospital were urged to provide separate accommodation for the insane and as a result the lunatic asylum in Parliamentary-road was begun in 1810 and finished in 1814. In 1842 it was found to be too small and Gartnavel Asylum was erected. Woodilee Asylum was erected in 1875 and Gartloch and Hawkhead Asylums in 1897. The asylum in Parliamentary-road began to be utilised as the town's hospital in 1843. The first municipal fever hospital was the one in Kennedy-street which was erected in 1865 The fever hospital at Belvidere was erected in 1870 and that at Ruchill in 1899. The Glasgow hospitals, including the convalescent homes, now provided no less than 8000 beds for the population of 1,000,000 inhabitants.

BRADFC [illegible] meeting of [illegible] Althorp, th [illegible] Hime made [illegible] Milk in the Feeding of Infants. He strongly condemned the growing custom by which women in comfortable circumstances refrained from suckling their children and substituted artificial feeding. Although the chemical composition of human milk might be more or less closely imitated by [illegible] was made particularly to the antiseptic action of the serum albumin of human milk on the bacillus coli and it was said that this was lost when humanised milk was used. In regard to the sterilisation of milk by heat Dr. Hime pointed out that in most cases many hours elapsed before the milk came into the hands of the consumer and that notable bacteriological and chemical changes might often take place in this time, so that even though the milk were sterilised yet toxins had been formed which could not be got rid of.—Dr. Hime also showed Nocard's Harpoon, designed to remove a fragment of the deep part of a tumour for examination.—Dr. W. A. Evans, Mr. Robert Mercer, and Dr. A. C. F. Rabag'iati took part in the subsequent discussion.—Dr. F. W. Eurich read notes on the Treatment of Gonorrhœa in the Male. He said at the outset that he relied exclusively on the demonstration of the gonococcus as the criterion of the presence of gonorrhœa. He advocated the use of injections of protargol and depended but little on internal remedies. In cases which had become chronic he employed irrigation with protargol under a pressure of about 40 inches of water and said that it was important that the patient should make an effort to micturate while the irrigation was going on, in order that the whole urethra might be exposed to the influence of the antiseptic.

Reviews and Notices of Books.

Aperçu Historique sur l'Hygiène en Belgique depuis 1830 (History of Hygiene in Belgium since 1830). By Professor and Dr. HYAC KUBORN, President of the Royal Society of Public Medicine and of Medical Topography of Belgium. Second edition, revised and enlarged. Brussels: H. Lamertin. 1904. Pp. 339.

THIS volume is dedicated to the Eleventh International Congress of Hygiene and Demography which was held in Brussels last year and also to the fiftieth anniversary of the First International Congress of Hygiene which met at Brussels in 1852 At the first mentioned of these congresses Professor Kuborn presided over the fourth section, which dealt with the questions of industrial hygiene and therefore it is but natural to turn to the chapter in his work which is devoted to this phase of public hygiene. The result, however, is not encouraging. It is but a short chapter recording discussions and the pious wishes that have from time to time been expressed rather than a record of effective laws adopted and enforced. This was to be expected, for it is well known that Belgium is much behind the age with regard to industrial protective sanitary legislation. Nevertheless, Professor Kuborn is able to describe the still more deplorable state of affairs that prevailed some 50 years ago when, for instance, the only restriction to working in coal mines was that the children should be at least ten years old. Then in the unventilated cotton mills of Ghent the mothers and fathers so suffered that their children under ten years old were on an average from seven to nine kilogrammes lighter than the children of agricultural labourers. There were at that time more than 40,000 women who had commenced to work as lacemakers when only seven years old. Anæmia, leucorrhœa, deformities, and injured sight were the general results. In the spinning and other mills children worked from five in the morning to eight at night with three intervals for meals. Of course, their education was as neglected as their health There were hardly any institutions to relieve the misery thus engendered but in time benefit societies and various forms of insurances were organised. At last a Parliamentary inquiry was ordered and this investigation was prolonged for no less than five years from 1843 to 1848. Perhaps it might have lasted a little longer but for the revolutionary upheaval that shook all Europe at the latter date. Then, indeed, a Bill was actually presented by the Government but after a year's discussion, when the danger of revolution was not so evident, it was rejected by the Chambers. The medical profession loudly protested that the health of the nation was seriously compromised. In 1852 the First International Congress of Hygiene met in Brussels and in 1856 a Congress on Poor Relief and Charities further supported the demand for legislative interference with the work of women and children in coal mines, factories, and mills. Some of the mine owners themselves petitioned for a law rendering it illegal to employ boys in mines under the age of 15 years. Governors of provinces protested that the militia in mining districts were so stunted in growth that they could not be relied upon for military service. The Academy of Medicine especially investigated the diseases caused by overwork in coal mines during the years 1858 and 1860 and concluded in favour of forbidding both girls and women from working in the coalpits. In 1863 the proprietors of the Ghent cotton, flax, and silk mills themselves petitioned for a law regulating the hours of labour and some time previously the Chambers of Commerce had recanted their former opinion that protective laws would ruin the trade. They were now in favour of some sort of legislation. A new Bill was presented in 1859, another in 1863, and some Royal decrees were issued dividing industries into two categories, describing the dangers arising in each and conferring on the local authorities some powers to intervene and to impose regulations that might lessen these dangers. Then nothing further was done till 1884. As Professor Kuborn remarks, the legislature went to sleep for 20 years. In the interval countless thousands of workers were brought prematurely to the grave. In 1884, however, a public health service was organised—"Service de Santé, d'Hygiène Publique, et de la Voirie Communal." This is a sort of combination of the work which in England is done by the medical officer of health and the borough surveyor. A Royal decree of April, 1884, forbade boys under 12 and girls under 14 years of age to work in mines or factories and a much stricter control was exercised over the sanitary condition and ventilation of mills, factories, &c.; unwholesome industries also were better classified. In 1894, by the decree of Sept. 21st, the service of factory inspectors was enlarged and improved. No children could be employed under 12 years of age and no woman was allowed to descend into a mine unless she was 21 years old. Nevertheless, such remedies and improvements as have been effected are but patchwork efforts and many crying abuses still exist.

The first two chapters of the volume give a very complete and scientific account of the physical character of Belgium: its climate, its geology, its mineral springs, its sea-bathing and other health resorts, and the climate of its forest and mountainous districts, such as the Ardennes, and this is accompanied by a study of the vital statistics of the places described.

The next section of the work deals with the sanitary services: the medical schools, the vaccination services, the bacteriological institutes, the production of serums, the questions of drainage and rivers pollution, &c. Then we find an analysis of such sanitary legislation, the question of workmen's dwellings, of the control of food-supply, and of beers, wines, and spirits. The diseases of animals and the prevention of the contamination of shell-fish are thoroughly investigated. A chapter is devoted to the hygiene of the school and another to military hygiene. Finally, there are two chapters on infectious and contagious diseases and on the relief and treatment, the hospitals and asylums, intended to assuage the suffering of the poor. In regard to the control of prostitution Professor Kuborn regrets that this should be left to the discretion of local authorities and thinks that there should be a general law applicable to the entire country. He says that "the measures adopted by the town of Brussels have had for result a considerable reduction in the prevalence of syphilis in that capital. The great majority of cases that are seen at the clinic of the hospitals or in private practice are either strangers to the town or prostitutes who have managed to escape from the surveillance of the police."

Perhaps, and especially considering how much the question here raised has been the subject of contest and argument in England, we cannot better conclude this notice of Dr. Kuborn's work than by quoting his opinion. The distinguished professor says: "Generous minds in Belgium and in other countries have dreamed the dream that all control could be abolished. They invoke public morality, the dignity and the freedom of woman. The dignity of the woman who has voluntarily trampled under foot all sense of dignity has nothing to do with the question. As for freedom, do we not applaud the preventive measures that are taken against cholera, small-pox, plague, &c., though they certainly interfere with personal freedom? But anyone carrying on any sort of business is liable to police interference so that he should not sell to the public goods that are adulterated or in any way injurious. It would be a far better argument if it could be shown that the tone of public morality was lowered, but public morality is a thousand times more affected and injured when absolute freedom is granted to the trade in debauchery. Whatever has been done, preached, prescribed, debauchery has always existed and will continue throughout all time and in all countries. The course to be followed is very clearly marked out. In the family circle the child must be well armed and warned against the danger to come. As for the State, it must deal with the facts of the case. This is much, but there is a further consideration. Wherever the authorities have not interfered it has been seen that the terrible ravages of syphilis have spread widely. Then there rises, far and away beyond and above all doctrines, the great question of public and social hygiene, the grave injury done to the health of beings who constitute the family and will become the future generation." In the name of the children, if not of the adults, Professor Kuborn demands the strict application of the Contagious Diseases Acts. Dr. A. Devaux, Inspector-General of Public Health, Dr. E. Dupont, Inspector of the Army Health Services, and Professor U. Laho of the State Veterinary College have assisted in writing this "History of Hygiene in Belgium" and have contributed the chapters relating to their special functions.

Pheasants, their Natural History and Practical Management. By W. B. TEGETMEIER Fourth edition, enlarged. London: Horace Cox, *The Field* Office. 1904. Pp. 255. Price 7*s*. 6*d*.

A DETAILED account of the natural history, habits, food, and treatment of the various species of pheasants had long been a desideratum; this book was projected with a view to supply the want in a complete and comprehensive form. In the new edition the author has given us the natural history and general practical management, not only of the pheasants strictly adapted for the covert but also of the allied species which are best suited to our aviaries. The progress of exploration is continually bringing to light species of pheasants hitherto unknown. A few years ago the only pheasant breeding wild in England was the common species (Phasianus colchicus). Our coverts now possess the Chinese, the Mongolian, the Japanese, and the Prince of Wales's species, while Reeves's pheasant, well adapted both for sporting and culinary purposes, has been bred in the forests of Scotland. Our aviaries have also recently been enriched by the addition of the Amherst pheasant and others which by their exquisite beauty eclipse even the gorgeous colouration and elegant markings of the comparatively well known gold and silver varieties. Altogether 21 species are now known and to these may be added two species of the closely allied birds which have been placed in the genus Calophasis. These differ from the true pheasants in having

16 tail feathers and the lower back of the males transversely barred.

The fact that all true pheasants inter-breed freely with each other and produce fertile offspring may be accepted as proof that they are only superficially distinct from each other. It is now, indeed, difficult to find pure bred specimens of the Phasianus colchicus in this country on account of the frequent crossings with the Chinese pheasant.

The author first treats of the natural history of the pheasants generally—their food, habits, and nesting. Then follows the consideration of their management in preserves, the details of the different methods of feeding the birds, their protection from their numerous enemies, and the formation of coverts. These chapters are succeeded by an account of their treatment in inclosed pheasantries, the hatching of eggs, the feeding of the young birds, and the prevention and cure of their diseases. A detailed description of the different species adapted for turning out is also given and the work concludes with accounts of the ornamental specimens.

The pheasants constituting the genus Phasianus are readily distinguished by their tail feathers, which are 18 in number. Phasianus colchicus was certainly brought into this country at an early period, for it is mentioned in Dugdale's "Monasticon Anglicanum" that the Abbot of Amesbury obtained a licence to kill pheasants so far back as the year 1100. Although many attempts have been made for its domestication the pheasant still retains its primitive habits. Many amusing stories are related in this volume of the attempts to tame and to domesticate individual specimens. The value of the pheasant to the agriculturist is very considerable, as the birds destroy enormous numbers of insects, to say nothing of their liking for the roots of various weeds, but it would be absurd to deny that grain forms their favourite food. The chapter on the diseases to which pheasants are liable is an interesting one; the occurrence of lead poisoning among the birds which have escaped the battue is a curious sequence.

The book is illustrated from life with six coloured plates, 17 engravings, and many woodcuts. The merit of the illustrations is great. To those members of the profession who indulge in the rearing and shooting of pheasants we commend the volume—they will find all the descriptions bright and admirable and the advice practical.

Transactions of the Epidemiological Society of London. New Series. Vol. XXII. Session 1902-03. London: Williams and Norgate. Price 6*s.* net.

MEMBERS of the Epidemiological Society are reminded by the honorary secretaries that the publication of these Transactions has been recently transferred from Messrs. Shaw and Sons to the firm named above from whom copies of back volumes and of the index can be procured. The current volume is fully up to the high level always attained by these Transactions and the value of the present number is enhanced from the fact that abstracts of the discussions which follow the reading of each papers are furnished. As we invariably give a very full abstract of the papers communicated to this society we shall content ourselves here with a brief indication of the contents of the present volume. Lieutenant-Colonel A. M. Davies, R.A.M.C., discusses the Meaning of Climatic Diseases; Professor S. Delépine contributes a very valuable paper on the Bearing of Outbreaks of Food Poisoning upon the Etiology of Epidemic Diarrhœa; and Sir Patrick Manson is the author of a paper upon the Danger of the Introduction of Yellow Fever into Asia if the Panama Canal becomes an accomplished fact. Dr. Louis C. Parkes treats of the Prevention of Diphtheria in Children's Hospitals and Dr. J. T. C. Nash of the Seasonal Incidences of Enteric Fever and Diarrhœa. The subject of the Etiology of Leprosy was brought before the society by Mr. Jonathan Hutchinson and Mr. J. Nield Cook, one of the foreign secretaries of the society, contributes a paper on Bovine and Human Tuberculosis in India. Finally, the society in a highly appreciative obituary notice refers to its late President, Dr. W. H. Corfield. This volume contains numerous charts and tables and some valuable maps constructed by Mr. F. V. Theobald of the Natural History Museum, South Kensington, showing the distribution of the genus "stegomyia" (Theobald) in both hemispheres.

The Thompson Yates and Johnston Laboratories Report. Edited by RUBERT BOYCE and CHARLES SHERRINGTON, with H. E. ANNETT, A. S. GRÜNBAUM, BENJAMIN MOORE, RONALD ROSS, and E. W. HOPE. Vol. V., New Series, Part II. December, 1903. London: Longmans, Green, and Co. Pp. 107. Price 12*s.* 6*d.*

THE recently published number of the above reports opens with a well-deserved tribute to the generous founder of the Thompson Yates laboratories, the late Rev. S. A. Thompson Yates. The Liverpool School of Medicine was indeed fortunate in possessing so sympathetic a benefactor. Not only did he found and equip the buildings but he constantly helped to keep them effective and to maintain them. It would be well if natural science could rely on a large number of such benefactors. The death of Professor Nocard is also feelingly alluded to.

The medical reports open with one on Trypanosomiasis. The expedition sent from Liverpool to Senegambia in 1902 studied the parasites of this disease found in men and horses. In the paper before us the laboratory methods are first discussed. The section on human trypanosomiasis then follows. Beginning with an account of its distribution and prevalence, the report passes on to the clinical signs manifested. The peculiar symptoms noted were irregular patches of a congested or cyanosed character on different parts of the body, an œdematous condition most marked on the face below the eye, and in a slighter degree on the lower parts of both legs, acceleration of the respiration and pulse, bad appetite, and an irregularly intermittent temperature. The differential blood count is explicitly given, showing a constant increase in the eosinophiles, mast cells, and mononuclear elements, the proportional increase being greatest in the first and last. The report then passes on to the consideration of equine trypanosomiasis and here it is pointed out that a listless expression and a slight rise of temperature were always present; so constant was the slight rise in temperature that one of over 101° F. came to be regarded with the greatest suspicion as indicative of trypanosomiasis. The morphological characteristics of the human and horse trypanosome found in the Gambia are then portrayed. The measurements of the flagellum, the position of the micronucleus, the staining of the protoplasm, the undulatory membrane, and other points are described. Two forms were found in the horse, a long and a dumpy form. Though no constant morphological differences between the human and the horse parasite—more especially in the case of inoculated animals—could be detected, still the parasites usually seen in the blood of horses examined in the early infected stage presented marked differences in size and appearance from the parasite usually seen in the blood of the infected natives.

Next we come to the transmission experiments with the tsetse fly. Those on rats were always negative. Experiments were also made to determine the truth of the statement that the tsetse fly carries nagana from animal to animal in a merely mechanical way and that probably no biological change in the parasite intervenes. Two varieties of stomyx instead of glossina were used, with the result that no success was ever obtained in mechanical transmission. The results of inoculation of the Gambian human and equine trypanosomes in animals are detailed, rats and mice being used. From these experiments it would seem at present that the trypanosomes are not of the same species for the following reasons: the more chronic course of the disease produced by the human parasite in all animals; the fact that tame rats infected with the horse parasite certainly die from its effects whilst there is no evidence showing that the inoculation of the human parasite is the only cause of death in these animals; and, lastly, the modes in which the human and horse parasites appear and disappear in the blood of inoculated animals during the course of the disease are not the same. Thus whilst there is a marked periodicity of entrance and exit of the parasite in the peripheral circulation in rats inoculated with the human parasite, this is not marked in the case of the horse parasite. Again, the marked enlargement of the spleen and the presence of hæmorrhagic glands are characteristic features of infection by the horse parasite but are not present in the case of the human parasite. Lastly, the equine parasite in the early stage of the disease can be distinguished morphologically from the human trypanosome found in the native. Mr. Theobald then proceeds to describe a new culicid from Senegal, whilst Professor Ronald Ross contributes an interesting section on a new parasite in man, first found by Major W. B. Leishman, R.A.M.C.

Then follows a note concerning the discovery of the trypanosoma Gambiense. In this it is stated that the claims of Nepveu are incapable of acceptance "without the greatest reservation."

Dr. Glynn and Dr. Matthews in their paper describe the bacteria in public swimming baths. They find that the Liverpool baths compare with others in Lancashire very favourably; that the first-class baths contain fewer bacteria than the second-class; and that the organisms were more numerous in fresh than in salt water. They point out also various injurious effects that bathing in swimming baths may produce, such as nephritis, pneumonia, typhoid fever, diphtheria, and scarlet fever. Other effects are earache and lessening of the vitality of the individual. Liverpool would seem to be especially fortunate in the frequency of the change of water in its swimming baths and in the care and supervision exercised. The report closes with the description of a parasitic disease amongst haddocks. The whole of the report is rendered especially valuable by its well-executed engravings and the many references to the subjects contained in it.

LIBRARY TABLE.

The Municipal Year-book of the United Kingdom for 1904. Edited by ROBERT DONALD. London: Edward Lloyd, Limited. 1904. Pp. 508. Price 3s. 6d. net.—The preface of this useful work is dated Feb. 19th and we think that it was a pity not to delay its publication until after the results were known of the recent London County Council election held on March 5th, for as matters now stand the list of councillors given at p. 11 is quite inaccurate. Another little point which might be altered in next year's issue is the arrangement of the London boroughs. They are nominally arranged alphabetically but St. Marylebone and St. Pancras are placed between Stoke Newington and Wandsworth. If these names were meant to be indexed under the letter S they should, of course, have come between Poplar and Shoreditch as commencing with "Saint." As a matter of fact, we find on p. 396 these two boroughs indexed at the beginning of the letter S. Besides the ordinary information about the various municipalities there are articles dealing with the Education Act of 1902, the housing of the working classes, and other questions of interest.

New Inventions.

A HÆMOGLOBIN SCALE.

THE absorbent paper test in practical hæmatology, provided that the standards are trustworthy, is both simple and satisfactory in evidencing the state of the blood not only as regards genuine anæmic conditions but also in a number of other pathological circumstances. Dr. T. W. Tallqvist of Helsingfors, Finland, has devised a very convenient and accurate appliance for the purpose which consists of a book of absorbent paper divided into squares by perforations, and at the end of the book there is a scale of blood tints of varying degrees of intensity, the minimum being ten and the maximum 100. The normal condition is between 90 and 100 of the colour scale. In order to carry out the determination a square of the absorbent paper is detached from the book and brought to the drop of blood in such a way that it is absorbed slowly until the paper is saturated through. The scales of tints have a perforation in the centre in the form of a letter D but flattened, that is, it is bullet-shaped. The blood stain is placed underneath this perforation in the colour scale and its intensity is thus easily determined by placing it under the degree which corresponds exactly to the tint. The process should be performed in daylight. It is, of course, very important that the tints of the scale should be exact and constant and to that end Dr. Tallqvist personally supervises the printing of the tints before the scale is sent out for practical application. It is obvious that errors of reproduction might easily result which would detract from the accuracy of the method. As a matter of fact, we have found in a few simple experiments which we have made that the tints correspond remarkably with blood itself. Dr. Tallqvist points out that in addition to the assistance which this method gives in diagnosing anæmia it will by careful observation furnish other valuable information also. Thus when a moist ring round the coloured spot appears it denotes a great diminution in the number of blood corpuscles. The greater the diminution of corpuscles the broader is this moist transparent ring. The presence of the ring is thus in general, he says, an intimation that a graver anæmia exists than might at first be supposed, and it is in agreement with this that the phenomenon as a rule does not appear in chlorosis. Even when chlorosis exists to a considerable degree the diminution of blood corpuscles is not excessive, while in pronounced pernicious anæmia diminution is generally the rule. The absorbent paper test appears also to demonstrate the condition of the blood in leukæmia. In attempting to deposit the drop of blood on the absorbent paper a striking contrast to the way in which normal blood is taken up is shown in the fact that the blood in leukæmia is only reluctantly sucked up by the absorbent paper, so that an appreciable time elapses before the spot has dried sufficiently to allow the test to be made. On close scrutiny it will be seen that the shade does not accord with any of those found in the scale, for which reason an estimate of the intensity of the colour cannot be made. Dr. Tallqvist adds that "the great quantity of leucocytes in the blood must, it is true, be considered to belie the change in a physical condition of the blood which in such cases reveals itself. Only a great augmentation of the amount of white blood corpuscles such as we find in leukæmia is shown in the above named manner on the absorbent paper; possibly the changed condition of leucocytes themselves plays a part therein." This simple test, carefully standardised in the way described, places in the hands of the practitioner a very valuable instrument for diagnosing certain conditions of the blood. The test is very easily applied and the results obtained, when compared with a trustworthy scale, correspond remarkably well with those obtained by more complicated blood-testing apparatus. The scale, with a sufficient number of squares of absorbent paper, occupies no more space than does a thin pocket-book.

THE LANCET.

LONDON: SATURDAY, APRIL 2 1904.

War Office Changes: The Army Medical Service.

THE War Office Reconstruction Committee has now issued the third and final instalment of its report. Lord ESHER, Admiral FISHER, and Sir G. CLARKE have certainly lost no time in bringing their labours to a close and in formulating a complete scheme for army reform and the reorganisation of the War Office. The document is in most respects a masterly one but we are not called upon to write an appreciation of its general merits save in the most general terms. These will be weighed by politicians and by the public as they should be. We are mainly concerned with the position which is designed by the Committee for the Army Medical Service, for here we can claim to speak with knowledge of what is wanted.

The appearance of the third report has been awaited by us, therefore, with no little curiosity in order to ascertain what was to be this position, and now that we know we have to confess that the grave misgivings which we previously expressed instead of being dissipated have been accentuated. For the director-general of the Army Medical Service is to have no place in the new Army Council. The proposed new army system will commend itself to ordinary citizens because it is commonly employed by them in all great and successful industries and businesses. It takes into account our peculiar conditions and requirements, national characteristics, and habits of thought and work, instead of slavishly adopting and following some foreign method like that of the German army corps system, for example, which is suited to the conditions of Germany, but which is not necessarily suited to ours. Now it has to be borne in mind that as regards army medical reform Mr. ARNOLD-FORSTER'S predecessor in office, after very full and deliberate investigation, came to the conclusion that, both as a matter of serious national interest and as the result of recent bitter experience, the medical and sanitary services of the army should occupy a representative official position worthy of their very high and important responsibilities. What was then done by Mr. BRODRICK has now been undone. We wish that we could share in the feeling that if the new proposals of Lord ESHER'S committee are adopted the medical and sanitary needs of the army will be secured; but we fear that the constantly recurring evils and causes of public complaint, instead of being removed, are more likely to become stereotyped by placing the director-general under the adjutant general—a military member of the Army Council.

The third report is a voluminous and important document containing many excellent diagrammatic tables. Beginning with a covering letter to the Prime Minister and closing with a concluding section, both of which are written in a terse, and trenchant style, this final instalment of the report will be read with all the attention and interest attaching to the previous portions of it. Following a tabular statement—Table B—instituting an interesting comparison of the Admiralty system and the proposed War Office reconstitution we come to Section I. dealing with "the adjutant-general" and containing a reference to the duties assigned to his office as those to *personnel* in all that belongs to the care of the soldier in peace and in war. The work of this branch should, it is recommended, be divided into five main groups, one of the five being named "Medical and Sanitary Matters" and comprising the Army Medical Service. Briefly stated, it may be said that stress is laid on the importance of the sanitary service in peace and in war and the committee proceeds to meet the criticism that a place ought to have been provided for the director-general of the Army Medical Service, who was a member of the defunct War Office Council, by pointing out that the Army Council is not, and cannot be, a representative body as regards all the several departments. Sanitation in war and in peace is, the report states, closely bound up with discipline, and the proper position of the director-general of the Army Medical Service is, therefore, under the adjutant-general whose duties are specially connected with the person of the soldier. "We do not admit," says the report, "that, under this arrangement, the status and the power of the head of the medical services will be lowered. We believe, on the contrary, that his position will be considerably strengthened in peace and in war. The council as a whole is now responsible for the welfare of the soldier. It has full powers over the whole range of military requirements and there should be no danger that sanitary considerations will be neglected. The adjutant-general, as a member of the council, occupies a far stronger position than his predecessors and will be able to represent effectively the medical needs of the *personnel* of the army with which he is specially charged. Moreover, the director-general, if necessary associated with a civil representative of the Army Medical Service Advisory Board, should be summoned to the council whenever his advice and specialist knowledge are required." The committee considers, however, that it is desirable to strengthen the hands of the director-general as regards the control of his expenditure and that some discretionary powers of purchase should be given to meet pressing needs. We may add that the construction of all new barracks and hospitals is proposed to come under the civil member of the Army Council and that the Army Hospitals Committee should advise as regards designs, sites, and sanitation of barracks and hospitals. The Army Sanitary Committee is to be abolished as a permanent committee.

We cannot endorse the view of the committee that under its proposed arrangement "the status and the power of the head of the medical services" will not be lowered. But we take a much broader and more important ground than this—namely, as to what is best for the nation and for the public service. The matter is one of a very exceptional kind. Our contention is that from the nature of the case no adjutant-general, however able, nor anyone without special knowledge and training can be in a position to represent, much less to initiate, the medical, sanitary, and hospital requirements of the army. He must, so far as these are concerned, depend entirely upon the advice of others. The method of procedure seems indirect and roundabout. With regard to the Committee's injunction that the director-general, associated if necessary with a civil representative of the Advisory Board, should be summoned to the council "whenever his advice and specialist knowledge are required," we may remark that his advice might not "be asked for," be obtained too late, or not be accepted, but he would nevertheless not escape responsibility in case of failure. It becomes a very different matter, however, when the head of a large and important army department has a place officially assigned to him on a council. There can be no doubt about the immense loss of life entailed in war by preventable causes of disease; and if these are to be limited in future, and if our army hospital service arrangements are to be the best practically attainable, authority and power must bear some relation to responsibility and to the importance of the objects in view. We hold, therefore, that medical and hygienic considerations require to be represented independently, directly, and prominently in the councils of the War Office by some duly constituted medical authority; they should not merely reach it through the medium of any military member of the Army Council. We consequently regard the view taken by the committee in this portion of its report as a retrograde step so far as medical and sanitary considerations are concerned.

In other respects it may fairly be claimed for the scheme formulated by Lord Esher's committee that it is a self-balanced one, its several parts apparently holding well together and representing a sort of organic unity. But something more is, after all, required than facility of administration. The proposals in the report of the Esher committee and the Government action in regard to them will be sure to be discussed thoroughly in Parliament, and we hope that the points that we have raised, and various other questions relating to the Army Medical Service, about which much uncertainty seems to exist, will then be cleared up to the satisfaction of the medical profession.

Self-Medication.

Few things are more curious among the histories of the many delusions about single subjects which from time to time have afflicted individuals not otherwise apparently of unsound mind than those which relate to an unreasoning trust in the virtues of drugs and to an overpowering propensity for swallowing them. An eminent physician not long deceased was once giving evidence in a will case and on being asked by counsel what fact he chiefly relied upon as establishing the insanity of the testator replied without a moment's hesitation: "Chiefly upon his unquestioning faith in the value of my prescriptions." It might perfectly well be contended that this evidence failed to establish the point at issue and that faith in the prescriptions of a physician hardly deserved to be stigmatised in so severe a manner. But admitting this, there is still little to be said in favour of the sagacity, even if we admit the sanity in respect of disposing power, of the numerous people who spend money and thought over the business of physicking themselves and who usually, if not indeed always, bring this business to an unfortunate conclusion. We are indebted to a paragraph in the columns of our contemporary the *Daily Mail* for an account of an old lady upon whom an inquest has lately been held at St. Leonards and who is described as having been in the habit of taking every night "nine compound rhubarb pills, several mixtures, four tablespoonfuls of senna, three teaspoonfuls of cascara, and a quantity of magnesia." The description of the drugs and of the dosage cannot be said to be pharmaceutically exact. It would be interesting, however, to know whether the medicines taken were effective for their supposed purpose and whether the lady died from exhaustion from over-purgation, or whether they were really powerless to empty an overloaded large intestine; but this inquiry, after all, is only by the way. The real point of interest in the case is that a lady who as the widow of a officer in the army may be presumed not to have bee wholly uneducated and who is described as having "di liked doctors" should yet have been so enamoured of wh our ancestors called "doctor's stuff" as to swallow it i such prodigious quantities and with consequences so unfo tunate to herself. Is her case to be regarded as exceptiona or does she merely furnish an extreme example of a preva lent and growing popular craze ? Our fears lean toward the latter conclusion and there are only too many facts fro which it may derive support.

The whole tendency of what may be called popul pharmacy during the last few years has been in th direction of introducing to the public a great variety powerful medicines, put up in convenient forms, and adve tised in such a manner as to produce in the unthinking belief that they may be safely and rightly administere at all times and seasons, without any guidance fro medical knowledge and without any reference to the actu state of the recipient, as remedies for the popular nam of some real or supposed malady. All this, of course, ha been greatly promoted by column after column of advertis ment in magazines and lay newspapers; but we a compelled to admit that the medical profession cann be held free from some amount of blame in the matter from some responsibility for the way in which drugs hav lately been popularised and brought into common use a articles of domestic consumption. Medical men have failed we think, sufficiently to impress upon the public and upo patients that the aim of reasonable people should be to kee themselves in health rather than to be always straying, a it were, upon the confines of disease and seeking assistanc from drugs in order to return to conditions from whic they should never have suffered themselves to depart. Th various alkaline salts and solutions, for example, th advertisements of which meet us at every turn, and whic are offered to the public as specifics, safely to be taken without anything so superfluous as the advice of medica men, for all the various evils which are decribed by th advertisers as gout or as heartburn, or as the consequence of "uric acid," do unquestionably, in a certain proportio of cases, afford temporary relief from some discomfort or inconvenience They do this notwithstanding persistence in the habit or in the indulgence, whatever it may be, the over-eating, the want of exercise, the excessive consumption of alcohol or of tobacco, which is really underlying the whole trouble which the drugs are supposed to cure and which at the very best they only temporarily relieve, while they permit the continuance of conditions leading ultimately to degeneration of tissue and to premature death. This is the moral which it is, we contend, the duty of the profession to draw from the daily events of life. The natural secretions of the human stomach are acid and the acidity is subservient to the digestive functions. It cannot be superseded by artificial alkalinity without serious disturbance of nutrition; and the aim of treatment, in the case of all digestive derangements, should be to cure them by changing the conditions under which they arise, not to palliate them for a time by the neutralisation of acid, which may, indeed, give relief from present trouble, but which leaves unaltered the conditions upon which the trouble really depends. Those who look down the obituary lists of the newspapers will be struck by the fact that large numbers of people, in prosperous circumstances, die as sexagenarians from maladies to which various names are given but which are, as a rule, evidences of degeneration and of premature senility while many who pass this period go on to enter upon an eighth or ninth decade of life. The former class, we have no doubt, comprise those who have lived without restraint of their appetites and who have sought to allay some of the consequences thence arising by self-medication, while the latter class comprise those who have lived reasonably and who, if annoyed by imperfect digestion, have sought relief by ascertaining and by abandoning the errors from which it sprang.

The Attitude of the Legal Profession towards the Medical Profession.

IN a letter published in THE LANCET of Feb. 27th, p. 611, Dr. E. MAGENNIS, writing of the conduct of barristers in Ireland, deplored the disappearance of that courteous treatment of the medical witness which once characterised cross-examination but which at the same time did not prevent the most vigorous investigation of the facts, and he drew attention to the unwarranted impertinence, frequently amounting to positive insult, which appears to arise from the assumption that the medical witness must not only be prejudiced but ready to give perjured evidence on behalf of the party employing him. There are many who agree with Dr. MAGENNIS, and who will add that the discourteous treatment of the medical witness is not altogether confined to the Irish courts, although they may admit that such conduct is comparatively rare in England and that in either country it is not that of advocates of high standing and repute. Others, again, are ready to call attention to the contradictions of medical witnesses and to regret that in some instances these should be of a character to bring discredit to the medical profession. In this case, however, as in the others, the man who deserves blame is the exception rather than the rule; he is not one of those who should be taken as types of an honourable profession. The medical profession is at a disadvantage when we compare it with others which are called upon to supply expert evidence in courts of law, and this in more respects than one. Expert evidence is not evidence of fact, it is evidence of opinion based upon scientific knowledge. Medical men give evidence of fact when they speak in the witness-box as to physical conditions which have come under their actual observation; when they draw inferences from those conditions as to the duration of injuries, as to the amount of incapacity produced, or as to the cause of them so far as these points lie outside the limits of their knowledge, they then become expert witnesses. In the same capacity, for the most part, they testify as to the mental condition of persons of doubtful sanity. These are examples of occasions upon which medical witnesses express opinions which they are qualified to give but which may well differ from those of other equally well-qualified persons who have looked at the same facts from a different point of view or who, holding different opinions upon doubtful topics, have a perfect right to express them. All such witnesses are entitled to be treated by members of the bar with the respect due from one learned profession to another.

In most of the actions heard in courts of law there is a winning and there is a losing side, and sometimes the winner gains so easy a victory that it seems wonderful to onlookers that the loser should have been allowed by his advisers to go into court at all. Nevertheless, he has not seldom let himself be involved in litigation because he was advised by his counsel that he had a "good case." Sometimes a suitor, successful before the judge who first tries his case, may find himself taken to the Court of Appeal upon a point of law, a matter of expert opinion, and again the decision of the Court of Appeal may, upon the advice of counsel, be challenged in the House of Lords. The loser there will have to bear the costs of both the lower courts, and the cause of his liability will be to a great extent the conflict of expert opinion founded upon facts which are hardly in dispute. Barristers and judges if they are sometimes blamed in private for opinions found to be wrong are not publicly cross-examined with regard to them, nor are they at any time accused of having been influenced by corrupt motives. The legal profession enjoying such immunity, and conversant as they are with the honest differences of opinion which may exist upon obscure subjects, should remember that, although witnesses who form and who express opinions upon controversial topics must submit their views to be tested by relevant questions, they should never incur without good reason the suggestion of incompetence or venality. In one respect a peculiar disadvantage of the medical expert witness is shared by the lawyer, and this fact should be a bond of sympathy between them. Both have to form their opinions more or less upon information given to them by men and women who are frequently the persons most interested in the questions raised. The engineer gives his evidence, often contradicted by others, after inspection of the ground or machinery or other inanimate objects in relation to which it is sought. The connoisseur of pictures or the expert in handwriting has before him an inanimate article of the genuineness of which he has to judge without reference to its history, by the aid only of his knowledge and observation. The chemist by analysis compels the substance submitted to him to reveal the secrets of its composition. The medical man, no doubt, to a large extent can observe for himself but at the same time he is to a considerable degree dependent upon stories of sensations alleged to be present in his patient, which may be invented or grossly exaggerated, and upon untrue statements upon all sorts of material subjects. For example, in accident cases he may be misled as to the manner in which an injury was received, as to its immediate effects, or as to the condition of health of the injured person before the accident occurred. The legal expert, in a similar manner, not only has to give an opinion upon questions of law but often has to base a prediction as to the possible success of his client in litigation upon information as to the evidence to be given which may not be borne out when the witnesses come into court.

The disadvantage, however, which particularly affects the medical profession is that its evidence is the expert testimony which is most often required. We have referred to some of the commoner kinds of expert evidence other than that of medical practitioners, but the engineers, the experts in art, the graphologists, and the chemists, who give evidence during any year, can hardly approach in number the medical witnesses who have to give evidence in cases of all kinds and to submit to cross-examination. Hence it has happened no doubt that the suggestion of readiness to espouse a side has been more often levelled against the medical witness than against others. All evidence of opinion is liable to be contradicted by the holders of opposite views upon the same scientific subject. The differences of human opinion have been proverbial from very early times in the history of the human race. In the law courts they are most commonly observable among medical men, and in the law courts the temptation is always present to the advocate to discredit the evidence against him by all means in his power, even by the imputation of corrupt motives by word or manner. It is not, however, the duty of the advocate to win the cause of his client *per fas atque per nefas*. As Sir ALEXANDER COCKBURN avowed upon a well-known occasion, amidst the cheers of his brother lawyers, the arms which he wields he should use as a warrior, not as an assassin. It rests with the judges, and with the honourable men in their profession in Ireland and elsewhere, to see that none among them gives occasion for such criticism as that of Dr. MAGENNIS to which we have referred.

Annotations.

"Ne quid nimis."

THE STATE REGISTRATION OF NURSES.

IN an annotation which appeared in THE LANCET of May 23rd, 1903, p. 1463, we referred to a paper read at a conjoint conference convened by the Matrons' Council and by the Society for the State Registration of Trained Nurses. This paper dealt with the State registration of nurses as it affects Poor-law infirmaries. In the course of our remarks we said: "Neither has it yet been clearly shown that the public and the authorities of the two great nursing institutions (the hospitals and the infirmaries) have arrived at an agreement upon the desirability of State registration of nurses." We have now before us a manifesto signed by many leaders of the medical profession, by chairmen and other officials of hospitals, and by many matrons both of metropolitan and provincial hospitals. This manifesto says that the objects claimed for registration are benefit to the public who would be able to ascertain from the register the competency of the nurse employed and benefit to the "trained nurses" themselves who are alleged to be placed at a disadvantage by the employment of imperfectly trained persons. The manifesto continues: "We believe that these claims are mistaken and that any system of State registration would be detrimental to the public and harmful to the nurses themselves, for the following reasons." We have not the space at our disposal to give the reasons in detail but the protesters call attention to the fact that registration must be based upon some system of examination and that such examination would in no wise test the personal qualities upon which the main value of a nurse depends, such as good temper, manner, tact, discretion, patience, and unselfish womanliness. Already all important hospitals where nurses are trained give to those who are instructed in their wards and whose work has been well done certificates of service after the usual term of three or four years. Such certificates are sufficient testimony of technical knowledge and experience and would not be improved upon by registration or examination. Such are the main objections which the signatories put forward. The names of the signatories, among whom are Lord Lister, the Hon. Sydney Holland, Miss Eva Lückes, and many others who are leaders in their several spheres, cannot but add weight to the opposition already in evidence to the proposal for State registration.

THE RECENT EPIDEMIC OF SMALL-POX AT HALIFAX.

WE have received a copy of a report presented to the county borough council of Halifax by Dr. J. T. Neech, the medical officer of health, describing the epidemic of small-pox which occurred in that town during the year 1903. The report not only deals with the statistics of the outbreak but Dr. Neech makes some remarks on, and suggestions for, the prevention of epidemics of the disease which are well worthy of note. Two charts are given which are interesting in several ways. They show the number of individuals who were infected by two men in the early days of the epidemic. They also demonstrate the difference in the effect produced in the spread of the disease by early cases on the one hand and by cases further advanced on the other. He is of opinion that the virus of the disease when in the body may be confined to the eruption and may not be present in the blood stream or tissues generally and therefore he considers that it is necessary that there should be some abrasion of the skin over the eruption in order to allow of the escape of the virus. From this it would follow that with each succeeding day of eruption the disease would become more infectious. Dr. Neech adduces evidence in favour of this assumption. He instances cases in which the disease was detected in an early stage and no further cases followed. For instance, a young man developed an ordinary discrete attack of the disease; seven other persons occupied the house in which he lived, none of whom were infected. He describes another case, that of a man staying in a lodging-house. He was suffering from small-pox in the papular stage. He used the same towel as the other lodgers and six men were thus infected. Dr. Neech suggests that friction with the towel destroyed the epidermis over the papules and so the virus of the disease was deposited on the towel. The man subsequently visited certain public-houses and seven more cases were traced to him. The period of infection then corresponded with the commencement of the falling of the scales from his body. When the man was admitted to the hospital he acknowledged that the rash had been out a month. Careful investigation showed that he had been the means of communicating the disease to 40 people These facts corroborate the views generally held—namely, that small pox patients are capable of communicating infection to others, perhaps during the stage of incubation, certainly during the initial stage, right through the disease, till not a trace is left on the skin of desiccated pustules or scabs or of the subsequent desquamation. The infection, however, is considered to be much more virulent at certain stages of the disease than at others; it is most virulent during the later periods of the rash, when vesiculation, pustulation, and scabbing have occurred, and least so during the incubation stage. Dr. Neech gives some interesting figures which prove in a most convincing manner the value of vaccination. For instance, the following table is worthy of reproduction :—

—	Unvaccinated.			Vaccinated.		
	Cases.	Deaths.	Mortality per cent.	Cases	Deaths.	Mortality per cent.
Under five years ...	10	4	40 0	—	—	—
Over five years ...	30	1	3 3	101	1	0 99
Totals	40	5	12 5	101	1	0 99

Dr. Neech describes the treatment which was adopted and also offers some observations on the cost of the epidemic. The facts stated in the report, apart from the value of vaccination, go to show the great necessity that exists for early notification and isolation of cases of small-pox; that success in controlling an epidemic depends upon this; and that it is the unrecognised cases, presumably of a mild type, which spread the disease.

STREET AMBULANCES.

IN THE LANCET of March 19th, p. 821, we referred to certain proposals recently put forward by the Metropolitan Street Ambulance Association with regard to a plan for providing London with a street ambulance service. Mr. William Thorburn, who is deputy chairman of the medical board of the Manchester Royal Infirmary, has forwarded to us a cutting from the *Manchester Guardian* of March 23rd containing a scheme proposed by himself for a somewhat similar service for Manchester. London, owing to its unwieldy size and to its being not one town but about 20, labours under peculiar difficulties with regard to any organisation which has to deal with London as a whole. So far as we know there are only two organised bodies of this description, the one being the Church and the other the London County Council, and neither of them at present has undertaken an ambulance service. Mr. Thorburn's suggestion for Manchester is that one or more ambulances should be stationed at the infirmary or other points and that there should be telephonic communication with all police stations or police beats. When an accident happened the nearest police constable would communicate with the ambulance station by means of a telephone attached to an alarm post something like the present fire-alarm posts. The ambulance vehicle should be a horsed or motor carriage which should be always ready to start and which should be accompanied by a medical man of the standing of a house surgeon. The drivers should be members of the police force. Mr. Thorburn's scheme, it will be seen, does not differ much from that outlined by the Metropolitan Street Ambulance Association, which we published on March 19th except in the somewhat important point that it eliminates the fire brigade and substitutes the police. Also Mr. Thorburn's scheme provides for a constant medical service. This, we think, is a point which should be insisted upon for London. It would, of course, mean an increase in the junior staffs of the hospitals and here the money question comes in. There would have to be at least two, and preferably four, house surgeons who should be in readiness by day or night to go with the ambulance, and although the pay or the keep of a house surgeon is not a serious item yet the additional expense would fall hardly on a hospital which is generally not too well off as regards its finances. In Manchester, however, such problems would not be so difficult of solution and we congratulate Mr. Thorburn upon a well-thought-out plan which if carried out will, we imagine, be of great service.

EASTER EGGS.

THE custom of offering a gift of eggs at Easter still survives and it is not difficult to surmise in what sense the egg was taken to be a symbol. Nowadays, the custom unhappily has almost lost its former quaintness and dignity and presents of all kinds are made to assume the form of an egg. Even the real egg itself must be coloured to give to it a festive appearance consistent, as it is thought, with a time of rejoicing and so the symbol is vulgarised by painting the egg with an unnatural colour, such as a blazing red, a practice, moreover, which may be open to objection on hygienic grounds. There is no guarantee that the colouring matter employed is of natural origin and artificial colouring may easily contain poisons. The diversity of colours used for the purpose is such that the choice is almost certain to include some of the aniline derivatives many of which are poisonous, while others, though they themselves may be harmless, may contain adventitious poisons. The craze for an artificial brilliancy of colour brings its reward in the shape of copper peas, dyed milk, annatto-stained butter, sugar coloured with salts of tin, and sweets and jam with brilliant anilines. It is hardly surprising that there are those amongst us who envy the lot of our ancestors who lived and ate when simplicity was the order of the day and before it was conceived that natural and simple products could be "improved."

PURPURA PRODUCED BY THE UPRIGHT POSITION.

THE fact that fatigue and walking influence the development of purpura and may produce a relapse if the patient gets up too soon is recognised. At a meeting of the Société Médicale des Hôpitaux of Paris on Feb. 4th M. C. Achard and M. H. Grenet described under the name of "purpura orthostatique" the following remarkable case in which purpura was produced under the simple influence of standing and even of sitting, and independently of fatigue. A labourer, aged 32 years, with signs of softening at the apices of both lungs and a purpuric eruption on the legs, was admitted to hospital. The eruption was symmetrical and consisted of petechiæ and rounded ecchymoses on both legs. The pyrexia was slight and did not exceed 100 4° F. The patient complained of vague pains in the knees. He was put to bed for ten days and the eruption disappeared, leaving only a few copper-coloured stains. He then got up for three or four hours but did not leave the ward and scarcely walked at all. In the evening the eruption reappeared and he complained of fatigue and pains in the knees. He was kept in bed for eight days and the spots entirely disappeared. He then got up for two hours and the eruption reappeared in the evening. He went to bed for six days, at the end of which he sat in an armchair for three hours without moving about. In the evening several spots appeared on the lower part of the legs. He was kept in bed for eight days. When he got up he was very fatigued and complained of pains in the legs but the purpura did not recur. M. Achard and M. Grenet thought that the purpura was due to a special "fragility" of the vascular system which led to rupture of the capillaries under the influence of the increased blood pressure of the vertical position. But they also suggested that vaso-motor disturbances, provoked by slight change in the equilibrium of the circulation, played a part. Potain has shown that the extravasation of blood in purpura is always preceded by vaso-dilatation. At the following meeting of the society other speakers related cases of purpura in which a relapse was provoked by the patient getting up. M. Besnier, the dermatologist, long ago observed this fact and enjoined care in allowing patients to get up.

THE VICTORIA HOSPITAL FOR CHILDREN.

THE above-mentioned hospital, which was founded in 1866, has, like nearly every other hospital in London, found it necessary to expand its buildings and to make alterations so as to bring them into accordance with modern ideas upon hospital hygiene. The original hospital began its beneficent work in one of the old Chelsea manor houses, by name Gough House. As time went on an out-patient department and a nursing home were added, but the actual hospital building remained the same, the number of beds having increased from 32 in 1868 to 70 in 1890. In 1898, owing to a report by the medical officer of health of Chelsea, the number of beds was reduced to 42 and the committee then decided to erect new wards on a site which was formerly the garden of Gough House but of which the freehold had been acquired by the hospital. On March 25th and 26th these wards were thrown open to inspection and we can cordially congratulate the committee and its architect upon the result of their labours. The building is now complete and ready for immediate occupation. It contains in the basement a large and up-to-date kitchen, store-rooms, nurses' and servants' dining-rooms, and a passenger lift controlled by electrical power. On the ground floor there are two wards, each containing 16 beds. They are the "Louise Ward," named after the generous patron of the hospital, and the "Alfred and Leopold Ward," which was named by Princess Louise, Duchess of Argyll, in memory of the late Duke of Edinburgh and the late Duke of Albany. On the first floor there are two more similar wards, one named the "Cadogan Ward" after the president of the hospital and the "Farquhar Ward," named in memory of the late Mr. Harvie Farquhar, for many years chairman of the hospital and a most kind and generous supporter. On the second floor there are again two similar wards, one named the "Annie Zunz Ward," to perpetuate the memory of the wife of the munificent founder of the Zunz bequest. On this floor there is an outside staircase leading to an isolation block of three wards, containing four beds in each. Thus it will be seen that the new hospital contains 108 beds in all. Each ward is complete with kitchen, bathroom and lavatory, and in case of an infectious outbreak it can be shut off without affecting the rest of the building. The lavatory contains, in addition to the usual water-closet, a douche for washing out bed-pans and a cupboard with a flue in which vessels containing stools which have to be kept for inspection can be placed. The operating theatre is constructed on the most modern principles and is ventilated by fans which drive air through a water screen and over warm coils, so that it enters the theatre washed, warmed, and moist. An exhaust fan in the ceiling removes the air as used. There is also in the building a complete milk sterilising apparatus and also arrangements for sterilising or disinfecting dressings and mattresses and other bedding. There is in addition a complete x-ray department. Balconies are placed outside every ward and there is also a complete clinical laboratory. As mentioned in THE LANCET of March 26th, p. 885, a sum of £13,000 is still required, which the committee hopes to raise by means of a bazaar to be held in June. We can only wish all success to the committee's effort, for the hospital is certainly a well-built and well-planned institution.

IS EPILEPSY A FUNCTIONAL DISEASE?

IN the *Journal of Nervous and Mental Disease* for March Professor Allen M. Starr of New York draws attention to the importance of having a correct view regarding epilepsy. In medical text-books from the earliest times epilepsy has been classed as a functional disease and this view does not seem to have been questioned seriously. Yet a careful review of facts ascertained recently, says Professor Starr, seems to demonstrate the fallacy of the prevailing opinion and to prove conclusively "that epilepsy is usually, if not always, an organic disease." This conclusion is based upon a careful study of 2000 cases of epilepsy which have been seen personally and of which satisfactory records were kept. In the first place it was found possible to draw a fairly sharp line clinically between Jacksonian epilepsy and so-called idiopathic epilepsy. In Jacksonian epilepsy the attack is always recognised by the patient as one of a similar series and consciousness is not lost, at least in the earlier stages of the attack. Four types of Jacksonian epilepsy are recognised—viz., the so-called "motor" type in which the attack starts with a local spasm; the sensory type which is marked by a hallucination (generally crude) of one of the senses at the onset, followed by a temporary suspension of the power of perception in that sense; an aphasic type in which a sudden interference with the function of speech takes place, either in the power of understanding or in the power of uttering speech; and a psychical type in which dreamy states of the mind or imperative ideas dominate consciousness, arresting the normal flow of thought and often leading to automatic acts the object of which is not clear and of which no conscious memory remains. In all these types, says Professor Starr, we consider the Jacksonian attack a sure indication of local irritation of the brain cortex and a symptom of local organic disease. In many cases of idiopathic epilepsy (38 per cent. of Professor Starr's cases) the attack was preceded by a conscious sensation or aura. This aura was in many cases identical in character with the aura initiating a Jacksonian attack. The only difference between a Jacksonian attack of the "motor" type and an idiopathic attack was the extent of the spasm, which in the former began locally and involved only a portion (seldom the whole) of the body, whereas the latter involved the body in a general convulsion. Occasionally, however, the Jacksonian attack ran into a general convulsion. In the cases of idiopathic epilepsy examined 76 showed numbness in the arm, 27 numbness in the leg, 22 numbness in the face, and four showed numbness in the trunk. "Had these patients had a local spasm and not a general convulsion after the aura, we should at once have suspected a lesion of the sensori-motor area." Visual hallucinations were present in 68 cases, auditory hallucinations in 30 cases, and hallucinations of smell or taste in 14 cases of idiopathic epilepsy. "Had these patients not had a general convulsion following," adds Professor Starr, "we should have suspected a lesion in the occipital, or temporal, or uncinate convolutions respectively." The nitted fact that Jacksonian epilepsy is due to anic disease and the close resemblance in many es (about 23 per cent.) between the attacks of ksonian epilepsy and idiopathic epilepsy seemed to our the view that in these cases, at least, idiopathic *lepsy was due to actual organic lesions. Idiopathic* lepsy was often associated with mal-development of brain, the clinical condition being one of imbecility idiocy, hemiplegia of infancy, diplegia of infancy ttle's disease), or infantile paralysis of the cerebral e. Of 400 cases of mal-development of the brain lysed in his "Text-book of Organic Diseases," Professor rr found that 156 patients, or 39 per cent., were subjects epilepsy. Idiopathic epilepsy was a disease of childhood youth. Thus of 2000 cases, 622 developed before the of ten years and 755 between the ages of ten and 20 rs; that is, 68 per cent. developed before 20 years of age—mely, during the period of most rapid development of brain. When epileptics were carefully studied it was ally possible to find evidences of signs of mental d physical degeneracy (stigmata), particularly in those o had been epileptic from infancy or early childhood. e ancestral history of epileptics frequently revealed the valence among the parents and near blood relatives of ilepsy itself, alcoholism, tuberculosis, or serious nervous ease. On the contrary, the epilepsies of advanced life, ich are happily few in number (only 26 cases developed er the age of 50 years) could almost invariably be traced to docarditis and atheroma, and the patients were very prone suffer from attacks of thrombosis or cerebral hæmorrhage. om a consideration of these various lines of argument it emed to be probable, concludes Professor Starr, that ilepsy was an organic disease. In conclusion, it was inted out that the gliosis found by Féré and Chaslin in ilepsy, by Alkzeimer and others in epileptic imbecility, d recent studies by Pierce Clark and others concurred to ow that a diffuse cerebral gliosis underlay epilepsy.

THE LATE SIR EDWIN ARNOLD.

Sir Edwin Arnold, Oriental scholar, philosopher, poet, d journalist, has, in his seventy-second year, passed to where the Silence sleeps." His considerable merits as a et will certainly preserve his name in all records of glish literature. It may be that the "Light of Asia" ined a popularity by the novelty of its setting rather than the originality or subtlety of its thinking, but none the ss it was the work of a man of genius. But apart from his erits as a man of letters and an untiring worker in the rious fields of literature his memory will be cherished many members of the medical profession whom he umbered among his personal friends. For Sir Edwin rnold was an admirer of medicine and always found me to follow, as far as a layman might, the advance of edical science. In 1895 he delivered the introductory ddress and presented the prizes at the opening of the inter session at St. Thomas's Hospital Medical School. hat address bore evidence of the keen interest which he ok in medical progress. In it he spoke with praise and conlction of the work which had been done and of the benefits hich were likely to accrue from the pathological researches f the day, while the important rôle which proper nursing lays in the treatment of disease was fully recognised. It is an teresting fact that during the Crimean war Sir Edwin rnold wrote some verses to the founder of modern nursing—lorence Nightingale. These verses were incorporated in the ddress and then made public, we believe, for the first ime.[1] His attitude towards experimental physiology was nstructive. While holding strongly to the ethics of the eligion of Buddha, with its beautiful tenderness for all living creatures, yet he said in one of his speeches: "If to give my own life under torture would certainly lead to the saving of very many other lives I should hate and scorn myself if I had not the will so to die; and as between men and beasts I suppose it is true that we are 'more than many sparrows.'" *Sir Edwin Arnold was a versatile and brilliant littérateur* and a man of wide knowledge and many sympathies.' Such men are ever the friends of medicine. One of Sir Edwin Arnold's sons is a member of the medical profession and is Government medical officer to the sanitary authority and port health officer at Levuka, Fiji.

THE NORTH-WEST LONDON HOSPITAL.

WRITING in the *Times* of March 29th, Lord Rathmore, chairman of the committee of the North-West London Hospital, refers to the appeal which is being made for financial support to the hospital and states that Mr. George Herring, the treasurer, has most generously offered to add one-third to the amount received in response to the appeal. Mr. Herring is well known as a liberal benefactor of charitable undertakings. The Hospital Sunday Fund Supplement *to* THE LANCET *of June 6th, 1903, p. 1640,* shows that in each of the years 1899, 1900, and 1901 he gave £10,000 to the Metropolitan Hospital Sunday Fund and in the year 1902 a still larger amount. From his intimate acquaintance with the financial aspect of hospital work his advocacy of the claims of any particular institution must carry great weight.

ACUTE SUPPURATIVE THYROIDITIS.

ACUTE suppurative thyroiditis is very rare and usually is secondary to some infectious disease. In the *American Journal of the Medical Sciences* for January Dr. Henry Roth has recorded the following case in which it was primary. On Nov. 26th, 1902, a man, aged 40 years, was admitted to hospital. He was suddenly taken ill with a chill and high fever on Nov. 23rd and gradually became worse. On admission his temperature was 103·2° F. and his pulse was 128. He seemed in a state of profound sepsis, being cyanosed and sweating profusely. A diffuse tender swelling extended from the suprasternal notch to the upper border of the cricoid cartilage. The most prominent portion of the swelling was red but there was no fluctuation. Over the shoulders were engorged veins. The patient was breathing badly and could swallow only with difficulty. Acute thyroiditis of unknown origin was diagnosed. Under chloroform a median incision was made from the thyroid cartilage downwards for two and a half inches. When the muscles were separated the thyroid presented as a smooth, dark-blue body with a dull capsule. On incising it on the left side a few drops of pus escaped and areas of necrosis were observed. The wound was drained with iodoform gauze. After the operation the temperature rose to 107°. The patient became worse and died on the following day. At *the necropsy the thyroid gland was found to be enlarged* and swollen; the right lobe was more enlarged than the left and showed areas of softening. On microscopical examination the connective tissue was found to be infiltrated with leucocytes which obliterated the acini. In places there were areas of necrosis and abscesses. On inoculating agar from the thyroid gland the streptococcus was obtained in pure culture. As the thyroid gland has no duct it is little exposed to infection and is usually invaded from the circulation. According to Mygind, thyroiditis is most common in females in the second and third decades and rarely occurs in previously healthy persons or as the result of injury but usually complicates or follows typhoid fever, rheumatic fever, diphtheria, influenza, malarial fever, erysipelas, puerperal fever, sepsis, orchitis, or prostatitis; it may also occur during or after scarlet fever, pneumonia, and pyæmia. According to Robertson thyroiditis is most common after rheumatic or typhoid fever.[1] After the latter it is usually suppurative and may be due entirely to Eberth's bacillus. Thyroiditis may terminate in resolution, suppuration, or gangrene. Gangrenous thyroiditis is attended by severe symptoms and usually is due to streptococcic infection. In the case related above the local signs might have been produced by ordinary phlegmonous inflammation but the constitutional symptoms were too severe. The latter were perhaps due to interference with the thyroid secretion. Dyspnœa, dysphagia, and movement of the swelling with the trachea are usually present at some stage of thyroiditis. In suppurative thyroiditis early incision and drainage are imperative. This treatment was of little use in the present case because the patient came under treatment too late, when the constitutional symptoms were severe.

---

THE RECENT DISMISSAL OF ASSISTANT MEDICAL OFFICERS BY THE METROPOLITAN ASYLUMS BOARD.

OUR readers will recall the recent comments in the medical and lay press upon the arbitrary dismissal of certain assistant medical officers of the Metropolitan Asylums Board. We hear that the Board has now offered compensation to these gentlemen and that the compensation has been accepted. The Board, we think, would not have consented to pay anything to its ill-treated employés had it felt certain of the legality of its own position. A spirit has recently prevailed at the counsels of the Board which is inimical to the medical men who hold its appointments. Evidence of this spirit has been recently forthcoming and justifies our belief that nothing would have been paid to the dismissed assistant medical officers if they, or certain of them, had not made clear their intention of not tamely submitting to injustice. Economy is urged by the Board as its reason for slighting the medical staff. We beg to call attention to the result of this economy as evidenced by the payment of these sums of money in compensation. The feeling in the medical profession is growing strong in regard to the management of the Metropolitan Asylums Board and we hope that the Local Government Board will make it an early duty to inquire into the whole situation, for the policy of running counter to medical opinion may land the Metropolitan Asylums Board in a very inconvenient situation. If those of the managers of that Board who are responsible for the recent attitude of the Board towards its medical department should obtain control over the counsels of the Board the metropolis may be placed in the dangerous position of being left without adequate scientific service in the infectious hospitals. We wish that the Local Government Board would boldly take the initiative in the matter and would instruct its nominees upon the Metropolitan Asylums Board to give proper attention to the rights, the privileges, and the views of the medical staff.

A RETURN OF PERSONS EMPLOYED IN TEXTILE FACTORIES AND LAUNDRIES.

A SUPPLEMENT to the annual report of the chief inspector of factories and workshops for the year 1902 was issued last week. It contains a number of interesting details so far as classification could be made in regard to the textile industries. Applications for the returns were addressed to occupiers in January, 1902, but it is computed that about 100,000 returns were outstanding on the last day prescribed for their receipt. The general summary of persons employed in textile factories and laundries contains 15 tables. As regards textile factories the number of departments, owing to the greater separation of manufacturing processes in the return, far exceeded that of previous years. The number of persons employed, however, showed a further decline and this would have been more marked but for the fuller inclusion of non-textile departments in the textile returns for 1901. The decrease was relatively greatest in Ireland and least in England and Wales. The diminution in each of three groups—children (half-timers under 14 years of age), young persons (full-timers under 18 years of age), and adults—was more than sufficient to explain the total decrease of persons employed. The only class showing an increase is that of female adults. An increase is recorded in the trade groups "wool, worsted, and shoddy," "hosiery," and "lace," the chief decrease being in "flax, hemp, jute, and china grass," "silk," and "cotton " The falling off in half timers since 1889 is shown in Table VII. In regard to laundries the return embraces 1774 factory laundries and 3876 workshop laundries registered in the department. Of the total of 5650 the southern division (which comprises London, Kent, Southampton, and Plymouth) included 3860. The figures are not so large as those shown on the inspectors' registers, the return having revealed the closure of many small laundries. It is stated that the corresponding returns for non-textile factories and workshops are being prepared and will appear in due course.

THE SPOROZOA IN RELATION TO DISEASE IN MAN AND ANIMALS.

IN his fourth lecture[1] delivered at University College, London, on March 21st, Professor E. A. Minchin dealt with a group of the sporozoa known as the hæmosporidia which comprise parasites that live in the blood of vertebrate animals and man. They constitute a class of organisms important from the medical point of view, since some of them are the active causes of malarial and other serious fevers. The hæmosporidia resemble the coccidia in many respects, but the latter are parasitic only on the epithelial cells of the alimentary canal whereas the former live in the red corpuscles of the blood. The hæmosporidia multiply endogenously by the process of schizogony or fission, but under certain conditions their continued life is impossible unless they pass through the body of another host, generally a mosquito. Much of the life-history of the malarial parasite has been known for 20 years, but Schaudinn by his recent researches has revolutionised many of our ideas about the hæmosporidia and sporozoa generally. His investigations of halteridium, a species of hæmosporidia found in the red corpuscles of the owl and other birds, have shown that a flagellate stage exactly like that of the trypanosoma of African sleeping sickness occurs in the hæmosporidia. Following the classification of Wasilewski two classes of hæmosporidia are recognised—viz., the hæmamœbæ, which exhibit an amœboid phase in their life cycle, and the hæmogregarinæ, which are gregariniform and exhibit no amœboid phase. The first class, or hæmamœbæ, include the following forms: the hæmamœba malariæ of quartan ague discovered by Laveran, the hæmamœba vivax of tertian ague, and the plasmodium immaculatum of pernicious malaria (Grassi), all of which are able to affect man; the proteosoma præcox of birds (Danilewsky) which dwells within the red corpuscles, the plasmodium Kochi of apes, and the halteridium of birds, a. curved halter-shaped parasite found in the red corpuscles; the piroplasma bigeminis of cattle, which is the cause of Texas fever, and the piroplasma canis and the piroplasma equi which affect dogs and horses respectively. The second class, or hæmogregarinæ, include parasites which occur only in the blood of cold-blooded animals (reptiles and amphibians)—e.g., the drepanidium ranarum discovered by Lankester, the hæmogregarina stephanopii of the water-tortoise, and karyolysus, a parasite which lives on the red corpuscles of the lizard. The intermediate hosts of these parasites are various. Thus all the three varieties of malarial parasite are conveyed to man by mosquitoes or gnats, a species of culex (gnat) carries proteosoma and halteridium to birds, and ticks carry the piroplasma to oxen. The bites or punctures of these insects conveys the parasite into the wound or puncture in the skin. In the case of Texas fever the young ticks infected by the piroplasma from the ovum of their mother carry the disease to oxen and other animals on which they live. An ox infected with this parasite develops all the symptoms of Texas fever within 45 days, during which period the parasite is multiplying and growing within its blood until a stage of virulence is reached which culminates in the symptoms of this fatal malady. The malarial parasites are dangerous to man, especially at the periods of spore formation in the blood, when they are literally produced in millions and prove destructive to the corpuscles and dangerously toxic to the patient.

---

[1] References to the first, second, and third lectures will be found in THE LANCET of March 12th, p. 736, and March 26th, p. 889.

PARTIAL RESECTION OF THE ASTRAGALUS FOR CONGENITAL TALIPES VARUS.

MANY operations have been devised for the treatment of congenital varus of the foot and in Lorenz's classification there are as many as 14 groups of operations, most of them with several varieties. They include osteotomies, removal of one or more bones, and the removal of portions of one or more bones, and all these are in addition to the division of tendons and other "soft" structures. Lund seems to have been the first to suggest removal of the astragalus and he has been followed by several others, especially Erskine and Mason, who have devised modifications. Verebely removed with a sharp spoon all the cancellous tissue of the interior of the astragalus, so that the foot could be wrenched into position but the articular surfaces were not interfered with. Lücke and Albert advised removal of the head of the astragalus and Hüter excised a wedge-shaped piece of bone from the outer half of the neck of the astragalus. In the present number of THE LANCET is published a letter from Mr. A. W. Hayles of Pontnewydd, Mon., who relates a case of talipes varus which he treated by excising a wedge shaped piece of bone from the astragalus, the apex of the wedge being downwards. The result of the operation was very good, as ultimately the boy was enabled to run about. Mr. Hayles's operation seems to be a modification of Hüter's method and certainly deserves a trial in some of the milder forms of this deformity, but we should not expect it to prove successful in any very marked case of talipes varus.

THE medical officer of health of the Cape Colony states that for the week ending March 5th there were 8 cases of plague discovered at Port Elizabeth, all in coloured persons. There were 4 males and 4 females and 7 of them are dead. All the patients contracted the disease in tenements in Rudolph street. No other cases of plague in human beings were discovered throughout the Colony, but plague-infected rodents were found at Port Elizabeth and East London. Of 315 rats examined in the Cape Town and Harbour Board area none was affected by plague. As regards the Mauritius a telegram from the Acting Governor received at the Colonial Office on March 25th states that for the week ending March 24th there were no cases of plague. As regards Johannesburg 4 fresh cases were reported on March 29th.

THE third contribution to the report on "The Pollution of Tidal Waters, with Special Reference to Contamination of Shell-fish," by Dr. A. C. Houston, was issued this week. We understand that the bacteriological condition of the London water companies' intakes on the Thames is considered to be unsatisfactory. We propose to deal with this report in a future issue.

AT the next meeting of the Incorporated Society of Medical Officers of Health to be held at 8 P.M. on Friday, April 8th, at No. 9, Adelphi-terrace, Strand, London, W.C., a paper will be read by Dr. J. Howard-Jones, medical officer of health of Newport (Mon.), on the Control of Measles Epidemics, to be followed by a discussion.

THE annual dinner of the West London Medico-Chirurgical Society will be held at the Trocadéro Restaurant, Piccadilly, London, W., on Wednesday evening, May 4th, at 7 30. Communications should be addressed to Dr. Charles Buttar, 10, Kensington-gardens-square, W.

THE Lord Mayor, accompanied by the Lady Mayoress, aldermen, and sheriffs, will open the Fifteenth Universal Cookery and Food Exhibition at the Royal Albert Hall on Tuesday, April 26th, at 2 P.M.

IN the Court of Appeal on Tuesday the decision of Mr. Justice Byrne in which he declined to remove from the register the mark "tabloid" was confirmed and the appeal was accordingly dismissed.

THE annual dinner of the Pharmaceutical Society of Great Britain will take place on Tuesday, May 17th, at the Whitehall Rooms of the Hôtel Métropole, London, S.W., at 7 o'clock P.M. precisely.

DR. H. R. Fuller, physician to the late Duke of Cambridge, has been appointed by the King a Member of the Fourth Class of the Royal Victorian Order.

THE AMENDMENT OF THE WORKMEN'S COMPENSATION ACT.

MR. Arnold J. Greene of Wigan, who has had considerable experience of the working of the Workmen's Compensation Act, 1897, as medical adviser to the Northern Employers' Mutual Indemnity Company, has sent us a pamphlet containing notes and suggestions as to matters of interest to the medical profession in connexion with the administration of the Act. We understand that Mr. Greene is likely to give evidence with regard to this subject before a committee at the Home Office to consider proposed alterations in the existing conditions and his evidence may have been given before these observations appear, but the matter is one which concerns not only the medical profession but employers of labour and working men and the interested attention of a much larger section of the public may at any time be drawn to it. The original Act, which only applies to certain descriptions of work, has already been extended so as to benefit the agricultural labourer and its future application to all kinds of service, including sea service and even domestic service, must be regarded as by no means impossible. With the general effect of the Act most people are familiar; it provides compensation for the accidental injury or death of workmen based upon the actual loss in wages traceable to the occurrence. It also has brought into existence "medical referees" appointed by the Home Secretary for purposes connected with the Act, which are specified in its schedules and in regulations issued by the Home Office to govern its administration.

Mr. Greene's principal recommendations as affecting the medical profession have as their object the increasing of the usefulness of the medical referee, for reasons and by methods which he specifies. The instituting of medical referees, no doubt, was intended by those responsible for the

Workmen's Compensation Act, 1897, as a means of dealing with the conflict of medical evidence which was likely to arise in cases where the duration and extent of the workman's disability from work as well as the cause of it had to be taken into consideration and to be estimated with exactness, for under that Act there were not to be what the law knows as "general damages," the loss of wages alone was to be considered. The duties assigned to the medical referee, which Mr. Greene thinks might be enlarged, arise out of an option given to the workman who may go before him at an early stage in the case and out of the power possessed by the arbitrator to refer to him for report a case in which conflicting medical evidence has been given.

The first class of case arises in this way. Under Paragraph 3 of the first schedule of the Act a workman who has given notice of an accident shall, if so required by his employer, submit himself to examination by a qualified medical practitioner to be provided and paid by the employer. Under Section 11 he is under a similar obligation when he is in receipt of weekly payments under the Act—that is to say, the employer or the person indemnifying him (i.e., an insurance company) has the right of ascertaining, by employing a medical man for the purpose, whether the workman continues to be incapacitated. On this latter occasion, however, the workman has an alternative. If he prefers not to go before the employer's medical man, or goes and is dissatisfied with the certificate so obtained, he may go before the medical referee whose certificate as to the workman's condition at the time is conclusive evidence with regard to it.

On the occasions described it will be seen that, in the first place, the medical referee does not come upon the scene at all until weekly payments are being made—that is to say, until a fortnight at least has elapsed since the accident; and that, in the second place, the workman has the option of calling in the medical referee but the person liable to pay compensation has not. The medical referee can then give a certificate which will be conclusive as to the workman's condition when it is given, but although it may be known that medical men called in by the workman and employer respectively hold differing views only one party and not the other can prevent further discussion by obtaining such a conclusive certificate. It is to the latter point that Mr. Greene more particularly calls attention and he gives many good reasons why the workman in but few cases exercises the right given to him. These may be summed up by saying that the working man who has one medical opinion in his favour may count, if an arbitration is held, upon being awarded compensation, at all events up to the date of the arbitration. If, therefore, his claim is exaggerated and the symptoms which he professes to exhibit are assumed he has everything to lose and little to gain from a visit to an impartial and experienced observer who may give a conclusive certificate against him. It is with considerable force and justice that Mr. Greene recommends that it should be in the power of the person who compensates to refer doubtful cases to the medical referee as well as in the power of him who is claiming compensation and also that he should be called in as soon as possible. It scarcely seems to require demonstration that a medical man will not be able to determine whether certain alleged physical conditions have existed as the result of an accident many weeks or many months after it has occurred with the same confidence that he would have felt had he been summoned to see the patient directly notice of the accident was given to the employer. An instance of an actual case is given by Mr. Greene in which a workman sustained a simple fracture of the leg in May, had his compensation stopped in October, and in March of the following year sought for renewal of compensation, supported by a certificate of a medical referee to the effect that he was suffering from a compound fracture of the leg and from injuries to the shoulder, both the result of the original accident. In order to defend this claim the employers had to go to arbitration in May, a year after the event, on the point that the injuries were not obtained in their employ, and the county-court judge had consequently to refer the case to the medical referee for the reconsideration of a certificate which according to the Act was final. The result of the proceedings was that the man was found to have had a simple fracture, as already known by his employers, and the alleged injured shoulder was eventually put down to alcoholic neuritis. It can hardly be disputed that in order to enable a medical referee to give a certificate with certainty upon any case he should have seen it at the earliest possible stage and, as Mr. Greene properly points out, he should hear not only the workman's statement but that of his employer in order to form a correct opinion as to the nature of the occurrence. An untrue statement by the workman that he has been insensible for three days after the accident or in bed for six months may now be made before the medical referee without anyone being there to contradict it.

With regard to the part taken by the medical referee where there is an arbitration two rules are to be noted: "Before making any reference—i.e., to the medical referee—the committee, arbitrator, or judge shall be satisfied, after hearing all medical evidence tendered by either side, that such evidence is either conflicting or insufficient on some matter which seems material to a question arising in the arbitration and that it is desirable to obtain a report from a medical referee on such matter." "In any case of special difficulty the judge or appointed arbitrator may require the attendance of the medical referee at any proceedings in the arbitration subsequent to the receipt of the report (i.e., of the medical referee's report), at a date and hour to be arranged, and the medical referee shall attend accordingly, but this regulation shall not authorise the medical referee being called as a witness." It will be observed that the medical referee is not introduced into the proceedings for the purpose of clearing up the doubt which may naturally arise in the mind of a lay arbitrator until after the hearing which should close the proceedings has taken place. Mr. Greene suggests that on the application of employer or workman a medical referee should sit with the arbitrator as assessor, on the grounds that he would thus be better able to advise the arbitrator from a medical aspect and that he might sometimes be able to clear up a doubtful medical point by a judicious question. Mr. Greene is of opinion that the occasion for such assistance by the medical referee would not often arise and that is, no doubt, why he suggests that he should only be present at the request of one of the parties. It is, however, so difficult to foresee what points may arise and what unexpected evidence may cause unlooked-for differences of opinion that it might fairly be contended that the presence of a medical referee was desirable in all cases where the nature and extent of the workman's injuries were not already ascertained beyond dispute. Any alteration in the rules which tended to introduce finality at as early a stage as possible in the proceedings should be welcomed by both parties, so long, of course, as possible injustice arising out of inevitable error was guarded against.

With regard to the personal qualifications and position of the medical referee Mr. Greene recommends that he should be the best man obtainable, rendered independent by being debarred from private practice and remunerated with an adequate salary. He suggests that recourse might be had to such men as have retired through the enforcement of an age limit from active connexion with the large hospitals and adds the recommendation that experience in ophthalmic surgery should form part of their qualifications. He would divide the country into areas of from 2000 to 4000 square miles, according to population and to the occupations of the population, and he goes into calculations based upon figures within his experience as to the number of cases which could thus be dealt with and which would be likely to occur. He points out that the services of the medical referee need not be confined to the Workmen's Compensation Act but that he could afford advice upon other occasions where medico-legal points arose.

Mr. Greene also draws attention to the possibility of improvement in other matters connected with the practical working of the Workmen's Compensation Act outside the office and duties of the medical referee. He points out the desirability of fixing a definite time limit within which the workman must take proceedings. At present he must claim compensation within six months but, having done so, may delay his request for arbitration for an indefinite period. Mr. Greene would permit the employers' medical representative to be present at a post-mortem examination held by order of the coroner in cases of death likely to lead to a claim for compensation. He refers to the hardship arising indirectly through the Act with regard to old, weak, and diseased workmen, owing to their predisposition to sustain injury or to continue incapacitated in consequence of it and predicts that a medical examination of all workmen engaged will some day be necessary. He discusses the difficult question of the workman who refuses to submit to a simple and obvious surgical operation and who by his refusal may continue in a condition of disablement while at the same time he enjoys a pension paid by his employer. He also refers to the treatment of workmen by unqualified persons and to the danger of their injuries being thereby increased. For example, the injured workman improperly treated by a herbalist or other quack may suffer from blood poisoning and may require his employer to pay for a prolonged illness or his relatives may claim compensation for his death. Mr. Greene approves of the retention of the rule by which the workman can claim no compensation for the first 14 days after his accident and whereby he is discouraged from exaggerating trifling injuries. He illustrates his point with figures An indemnity company compensating in respect of 34,601 workmen, but not paying for the first fortnight, had 1338 claims made against it in one year. An accident club in the same locality with 45,792 members, paying compensation for the first fortnight, including, of course, injuries of less than a fortnight's duration, had 8493 claims made against it in the same period. The workman who has once begun "to play" and has thereby got his muscles and the skin of his hands soft is obviously under a temptation to continue his rest for the longest period possible, and the employer at whose expense he does so naturally regards the payment of "compensation" where it is not necessary on account of disablement as unjust to himself.

The possible amendment of the Workmen's Compensation Act is, as has been suggested above, a matter of interest to all employers and workers besides those now affected, but, whether its scope is to be enlarged or not, it is desirable that the procedure under it should be made as far as possible, rapid, inexpensive, and conducive to just and fair results. At present the Act has not been a success, for such results as have been attained under it have led to an expense in litigation, through necessary appeals upon obscure points, that has been almost without parallel, and cases which have pressed with undue hardness upon the employer or, less frequently, upon the workman have not increased that goodwill and mutual confidence between master and man the existence of which is of great importance in a manufacturing community. The circumstances in which medical men appear as witnesses are often unsatisfactory and, as has been shown above, under the Workmen's Compensation Act the conditions imposed by law are such as to increase rather than to diminish the contradictions of medical opinion which are inherent in all legal proceedings when compensation for alleged injury is claimed and disputed.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

THE annual general meeting of the members of the Medical Graduates' College and Polyclinic was held at 22, Chenies-street, London, W.C., on March 28th, Dr. C. THEODORE WILLIAMS being in the chair.

Dr. WILLIAMS, in moving the adoption of the report and balance-sheet, said that the College was continuing its work satisfactorily. He regretted that they had for some time lost the services of Sir William Broadbent as their president, but he was glad to announce that that gentleman would take an active part, as he had always done, in their clinics. Dr. Williams then made a sympathetic reference to the death of Sir William Kynsey who had been a vice-chairman of the Polyclinic. Referring to financial matters, he announced amid applause that Mr. James Berry had been elected treasurer, which, he said, was a sure sign that they were to have good help in finance The annual report showed that the number of members was keeping up very well. There was a slight falling off at one time when there was some doubt as to the future of the Polyclinic but the number had risen immediately after that under the able management of the secretary, Captain A. E. H. Pinch, with the result that it was hoped that the number of members shortly would reach 1000. Dr. Williams, continuing, said he did not think that the great advantages of the Polyclinic were sufficiently widely known. No other establishment offered the same kind of teaching that was to be found in the clinics held at 22, Chenies-street. The great point was that everything was arranged for the use and advantage of medical practitioners. He did not know of any place where a medical man could have the privilege in one year of examining something like 1000 cases and of hearing them demonstrated. The laboratory work at the Polyclinic under Captain Pinch had attained great perfection and it ought to be known that members would get their work done just as well by sending specimens to be examined at the Polyclinic as if they were forwarded to any similar research association. In regard to the composite course of lectures, its success was assured because no fee was to be charged in future. He did not know of any institution which gave its members 186 extra lectures without payment. Lectures were given by men of undoubted authority who had made certain subjects their own and who constituted a sort of court of appeal. In fact, someone had told him that there was only one appeal beyond the lecturers at the Polyclinic and that was the post-mortem room. Dr. Williams then referred with approbation to the change that had been made under the editorship of Dr. C. O. Hawthorne in the *Polyclinic Journal*. He concluded his remarks by describing the steps which had been taken to place the finances of the Polyclinic on a sound basis.

Mr. JAMES BERRY having seconded the motion, it was put by Dr. Williams to the meeting and carried unanimously.

A vote of thanks, proposed by Dr. G. CRAWFORD THOMSON, seconded by Dr. J. R. GABE, was duly passed to the retiring members of the council: Mr. S. Cathcart, Mr. W. H. A. Jacobson, Dr. Boyd B. Joll, and Dr. F. J. Payne.

The meeting then confirmed the interim election of Mr. E. Clarke and Dr. Hawthorne as members of council and the following five gentlemen were elected members of council: Mr. G. Lenthal Cheatle, Mr. J. Jackson Clarke, Dr. A. P. Luff, Mr. C. G. Drummond Morier, and Dr. H. Campbell Thomson.

A cordial vote of thanks to Dr. Williams concluded the meeting. It was a general matter of congratulation that peace and harmony had prevailed in place of the strenuous discussions which had characterised the last few meetings.

THE
MINERAL WATER OF KARA-HISSAR-I-SAHIB.

WE have been favoured by His Excellency the Turkish Ambassador with a case of samples of this interesting mineral water, the source of which is a spring in the district Kara-hissar-i-Sahib, in the province of Broussa in Asia Minor. We understand that the water has been employed in the Hamidié Hospital for Women and Children, Constantinople. The temperature of the spring is 17° C.; the water is perfectly clear and bright and has an agreeable alkaline taste. It has a cleansing effect in the mouth and contains a slight excess of carbonic acid gas. On analysis the following results, given in grammes per litre, were obtained in THE LANCET laboratory:—

Sodium carbonate	2 24
Calcium carbonate	0 20
Sodium chloride	0 23
Borax	0 01
Total	2 68

The total saline constituents thus amount to 2·68 grammes per litre. The carbonic acid gas being in excess, the carbonates obtained on evaporation are present in the water as bicarbonates. There were present also traces of lithium salts but there was no evidence of organic impurity. A noteworthy constituent is borax. Generally speaking, this mineral water resembles in composition the waters of St. Galmier, Gieshubler, Fachingen, and Ems, all of which are reputed to be useful in diseases of mucous membranes. The alkaline waters of Fachingen, which resemble in particular that of Kara-hissar-i-Sahib in containing chiefly carbonate of sodium and chloride of sodium, are employed in diseases of the kidney and bladder. In some clinical reports emanating from the Hamidié Hospital it is stated that the water has been given with good results in chronic gastric affections, and in bronchial catarrh and also in affections of the bladder—e g., cystitis. This favourable action of the water may be referred to the alkaline salts and lithium which it contains, while borax is doubtless an important contributory factor. The water is exported in bottle, but there is no reason why the spring should not form the basis of a hydro-therapeutic establishment on the lines of the continental watering places mentioned above.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

AN extraordinary Comitia was held on March 28th, Sir W. S. CHURCH, Bart., K.C.B, the President, being in the chair.

The PRESIDENT delivered the usual annual address in the course of which he referred to the lives of eight Fellows who had died during the year—namely, Dr. E L. Birkett, Dr. W. S. Playfair, Dr. W. H. Corfield, Dr. J. Tatham, Dr. Alfred Sangster, Dr. J. W. Hue, Sir E. Sieveking, and Dr Alexander Davidson. The President then referred to the distinctions which had been conferred on certain members of the medical profession and to the award of medals, prizes, and scholarships connected with the College. He also detailed the lectures which had been delivered, especially drawing attention to the Harveian Oration and to the first FitzPatrick lectures. In speaking of the endowments presented to the College during the year he once more thanked Dr. Horace B. Dobell and Dr. George Oliver for their generosity. He then reviewed some of the work accomplished by the College and the many important committees which had been appointed during the year.

Dr. J. E. POLLOCK proposed that the College should express its thanks to Sir W. S. Church for having acted as President during the past five years and also for his address and should request permission to have it printed.

This motion was put to the College and carried by acclamation.

Sir W. S. CHURCH returned thanks to the College and acceded to the request to have his address printed. He then vacated the chair.

The Registrar (Dr. E. LIVEING) read the regulations which govern the election of President and the election was then proceeded with. At the first ballot the following was the result: Sir William S. Church, 44 votes; Sir William Broadbent, 42; Sir R Douglas Powell, 35; Dr. P. H. Pye-Smith, 29; Dr. W. H. Dickinson, 3; Sir Dyce Duckworth, 2; Professor Clifford Allbutt, 2; Dr. J. F. Payne, 1; Dr. F. W. Pavy, 1; and Dr. Robert Barnes, 1. A second ballot was then taken with the result that Sir William Church was elected, receiving 91 votes while Sir William Broadbent received 69.

The charge was delivered by the Senior Censor (Sir DYCE DUCKWORTH) and the PRESIDENT pledged his faith to the College.

Sir W. S CHURCH thanked the College for the honour conferred upon him in being again elected President.

A Licence to practise physic was granted to Colin Alexander Campbell, M B. Toronto.

The College seal was set to a "Declaration of Trust" accepting a sum of £2000 from Dr. George Oliver for the endowment of "The Oliver-Sharpey Lectureship or Prize" on the terms agreed to at the last meeting.

The following communications were received: 1. From the Colonial Secretary, moving the College to establish an examination and diploma in tropical medicine. The matter
ras referred to the Committee of Management for report.
. From the clerk of the Privy Council, asking on behalf of
he "Physical Deterioration Committee" observations from
he College on a scheme for establishing a permanent
nthropometrical survey of the United Kingdom. The
quut was referred to the same committee that reported on
, and ysical Disability of Recruits," the President to
fer the two new members in place of Dr. G. Vivian Poore
a of a c J. J. Pringle who were unable to serve. 3.
e result e secretary of the Royal College of Surgeons
ave had d, reporting certain proceedings of its Council
yers, an lth and March 10th. 4. From the English com-
down to the International Congress on School Hygiene
at Nuremberg, April 4th to 9th, inviting the
point a representative on the committee and to send delegates to the Congress. The President announced th
he had nominated Sir Lauder Brunton to act as delega
of the College and Dr. F. Warner to serve on the commit
5. From the secretary of the Sanitary Institute,
College to send delegates to the annual congress t
at Glasgow, July 25th to 30th. It was resolved
delegates to the congress, the names to be announc
next Comitia.

After some further business the PRESIDENT diss
Comitia.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 1

THE FRENCH SYSTEM OF SURGICAL EDU CONTRASTED WITH THE ENGLISH.[1]

FOR the following accurate history of the Fren
of surgical education, we are indebted to Mr. BENN
for several years, taught anatomy in Paris, and
qualified to write on the subject.

In 1792, the National Convention decreed the
of all universities, colleges, corporations, &c.
France. However, before the expiration of t
found it indispensable to provide for the
medical men, and in consequence Fourcroy
deputed to devise some system which, it
admitted, should be founded upon the

REPORT OF THE PUBLIC HEALTH COMMITTEE OF THE METROPOLITAN BOROUGH OF POPLAR.

ON Feb. 26th, at the meeting of the public health committee of the metropolitan borough of Poplar, Mr. Frederick William Alexander, the medical officer of health, reported upon the introduction of a case of small-pox into the metropolis as follows:—

Small pox.

A coloured man suffering from small-pox walked into the oplar Hospital on Feb. 18th and could give no proper account f himself except his name. He stated that he had been leeping with other coloured men in a lodging house near a hurch in Poplar. The ambulance nurse, before taking the tient to the South Wharf, endeavoured to find out his ress by calling at several lodging-houses but the patient not known. As soon as the authorities at Poplar Hospital honed to the public health department that the case been removed the chief disinfector commenced to call seamen's lodging-houses and common lodging-houses. ondon County Council was communicated with so that pspectors of the common lodging-houses might make hs. The medical officer of the South Wharf was ed to and asked to put further questions to the who was evidently a sailor) as to the name of his where he came from. The patient did not know of his ship but he stated that he had come ort News. The medical officer of the Port was immediately telephoned to and asked to ies as to all ships which had arrived from vs. On the 19th the Port of London medical ned that the patient, with two other coloured other men, all cattlemen, had left the in Victoria Docks on the 16th but he where they had gone to. In the meantime ector, Mr. Johnson, and the chief disinfector airies at the seamen's and common lodging- hnson found that the patient had slept at -house in High-street, Poplar, with the on the nights of Feb. 16th and 17th. e London County Council found some of " in common lodging-houses in White- oloured men were revaccinated and taken lter in Glaucus-street to be bathed and to lisinfected. The men spent the night at there is no male attendant the chief the shelter. The bed and bedding from common lodging-house were removed to pparatus and the three rooms were dis- washed.

further reported to the public health letter received from the London County the question of the amendment of the vs:—

. IV., Cap. cvi., 6 & 7 Will. IV., Cap. 37).

o the letter of the clerk of the London ating that the Council has under consideraof the desirableness of the Council seeking or the better protection of the public than the existing law as regards the sale of nder had the following remarks to offer. d sold in the City of London and liberties in ten miles of the Royal Exchange under eo. IV., Cap. cvi., which was passed on 2, and outside the ten-mile radius under the 6 & 7 Will. IV., Cap. 37, which was passed on 36. The statutes are almost identical. If the of George IV. be repealed and the adulteration ions be re-enacted Mr. Alexander suggested that the lteration provisions of the Act should be enforced by the tary authority. The adulteration sections of the Geo. IV. Act, being Sections ii., x., xi., xii., and xiii., and the penalty provisions which follow, should be re-enacted in modern language. A section should be inserted to the effect that meal or flour of wheat, barley, rye, oats, buck-wheat, Indian corn, peas, beans, rice, or potatoes should be stored separately in properly marked sacks or bins. The properly appointed officers of the local authority should have the right to enter any premises and without purchasing to take any samples of dough or bread, or samples of meal or flour of any grain from any sacks or bins, and to submit the same to the public analyst, and, if found to be adulterated, proceedings should be taken. The taking of samples in this manner, without purchasing, would not be a new procedure, as inspectors have power, for the purposes of analysis, to take without purchasing samples purporting to be butter and cheese—butter under Section 10 of the Margarine Act, 1887 (50 & 51 Vict., Cap. 29), and cheese under the Sale of Food and Drugs Amendment Act (62 & 63 Vict., Cap. 51, Section 5). The baker should be protected by warranty in a like manner as the vendor is protected under the Sale of Food and Drugs and Margarine Acts and then Sections x., xi., and xii. of Act of 3 Geo. IV., Cap. cvi., would, if re-enacted, be well met. The warranty would also apply to Section xii., so as to protect those persons who sell but do not make bread. So far as Section xii. is also concerned, which enacts that bread made of mixed meal or flour is to be marked with a large Roman M, it would be better that when bread is made wholly or partially of the meal or flour of any other sort of corn or grain than wheat, or of the meal or flour of any peas or beans, to have all such bread marked or stamped with the name of its component parts so as to be intelligible to the public who do not know what a large Roman M means. Potatoes should be added to this section as these ingredients are included in 6 & 7 Will. IV., Cap. 37, Section 10, which is similar to 3 Geo. IV., Cap. cvi., Section xii., but there is a proviso in Section 10 of the Bread Act of William IV. which can be added and is as follows:—

> Provided always that nothing in this Act contained shall extend or be construed to extend to require any bread made of the meal or flour of wheat only, and in the making of which potato yeast shall be used, to be marked as hereinbefore mentioned.

The powers of entry should be on the same lines as those proposed in the Bill of the London County Council (General Powers), clause 27:—

> The sanitary authority of any sanitary district, or any officer or person duly authorised by them in that behalf, shall have the right to enter at all reasonable times any house, building, or premises in that district for the purpose of examining whether there is any contravention of this part of this Act or of any by-law made thereunder, or for the purpose of carrying into execution this part of this Act or any by-law made thereunder.

The suggestions were adopted by the council of the metropolitan borough of Poplar.

At the same meeting Mr. Alexander, with very great regret, reported the death after a short illness of Mr. F. J. Anthony, sanitary inspector and inspector under the Food and Drugs Acts and canal boat inspector for the Bromley North Division. Mr. Anthony died on Feb. 24th. Mr. Anthony had been in the service of the Poplar sanitary authority since 1880, a period of 24 years. He first acted as disinfector and having qualified himself by passing the examination of the Sanitary Institute he was appointed sanitary inspector to the Bromley North Division in June, 1893. During his 24 years' service Mr. Anthony had also charge of the infectious disease mortuary belonging to the council in Wellington-road. The medical officer stated that he always found Mr. Anthony a most trustworthy and fearless officer.

ASYLUM REPORTS.

London County Asylum, Bexley Heath (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 2079, comprising 1019 males and 1060 females. The admissions during the year amounted to 519—viz., 224 males and 295 females. Of these 483 were first admissions. Dr. T. E. K. Stansfield, the medical superintendent, states in his report that a female nursing staff has been substituted for male attendants in the male infirmary wards, "a change that has so far been in every way satisfactory. It has added materially to the comfort, the general well-being, and the successful treatment of the patients concerned. ...... The success justifies an extension of the principle, but unfortunately the structural arrangements of the asylum offer what at present appear to be insurmountable difficulties. This is a matter which, in my opinion, ought to receive very careful consideration when the plans of another asylum are being considered." Among the admissions melancholia was the form of mental disorder manifested in the largest number of cases (31·4 per cent.), mania was present in 26 per cent., and delusional insanity, principally of the paranœic type, in 10 per cent. General paralysis affected 40 cases, or 7·7 per cent. "The physical condition of the admissions as a class was poor, and many, indeed, were mere human wrecks on the verge of dissolution." A hereditary predisposition to insanity was present in 28 per cent. of the admissions, a neurotic heredity was present in 14 per cent., tuberculous parentage occurred in 11 per cent., and alcoholic heredity in 6·5 per cent. Evidences of syphilis were made out in 106 cases, or 21 per cent. of the total number of admissions. The forms of mental disease with which it was principally associated were general paralysis (31 cases), acute melancholia (20 cases), acute mania (14 cases), primary dementia (eight cases), organic dementia (five cases), and delusional insanity (five cases). "It will thus be seen that the relation of syphilis to general paralysis was out of all proportion to that of any other form of mental disease." Alcohol as a personal factor was considered to be present in the causation of 103 cases, or 20·5 per cent., and it was an associated factor in 24 cases each of syphilis and neurotic heredity. The number of patients discharged as recovered during the year amounted to 180—viz., 76 males and 104 females, or 8·6 per cent. of the average number resident. The deaths during the year amounted to 250, or 12 per cent. as calculated on the same basis. Of the deaths five were due to senile decay, six to cerebral hæmorrhage, seven each to epilepsy and renal disease, eight to colitis, nine to bronchitis, 11 to syphilis, 19 to pulmonary and other forms of tuberculosis, 32 to cardiac disease, 61 to general paralysis of the insane, and the rest to other causes. The Commissioners in Lunacy state in their report that the wards and dormitories were in excellent order throughout, that the patients were in a satisfactory condition as regards dress and personal neatness, and that the medical case-books and post-mortem records were intelligently and carefully kept. The committee of management states in its report that improvements have been made in the electric battery supplying the light of the institution, that a hospital villa is to be provided for male patients at a cost of £13,000, and that the amount expended on additions, alterations, improvements, and repairs reached the sum of £5721.

London County Asylum, Horton (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 958, comprising 537 males and 421 females. The admissions amounted to 2019—viz., 1028 males and 991 females. Of these 2015 were first admissions. Dr. F. Bryan, the medical superintendent, states in his report that of the whole number of admissions 1544 were transfers from other asylums. "The asylum is now practically complete in all its departments and in full working order. ...... The chief difficulty during the year has been the engagement of a trustworthy staff. While the admission of patients has been regular, the supply of attendants and nurses has been very intermittent. ...... I believe that we have now the nucleus of a very good staff." The number of patients discharged as recovered during the year amounted to 88—viz., 49 males and 39 females, or 9·2 per cent. of the average number resident. The deaths during the year amounted to 108, comprising 70 males and 38 females, or 12·3 per cent. as calculated on the same basis. Of the deaths two were due to epilepsy, three to colitis, four to renal disease, five to senile decay, nine to pneumonia, 14 to pulmonary and other forms of tuberculosis, 16 to general paralysis of the insane, 28 to cardiac disease, and the rest to other causes. There have been four inquests during the year. In three of these the jury returned the verdict of "Death from natural causes." In the fourth the patient, during an attempt at suicide by choking, died suddenly from syncope. The Commissioners in Lunacy state in their report that the asylum was opened for the general reception of patients from the County of London in March, 1902, and that it was designed to accommodate 2000 patients. A small isolation hospital for infectious cases forms part of the institution. "The organisation of the asylum," adds the report, "has made good progress," as was apparent at a visit made on July 15th, 1902. At a second visit on March 30th, 1903, the Commissioners state that the dress and personal appearance of the patients were found to be satisfactory, that the day-rooms, dormitories, and bedding were exceedingly well kept, and that the medical case-books were well and efficiently kept up to date notwithstanding the large number of admissions. As regards provision in case of fire it is suggested that arrangements should be made for a night watchman to be on continuous service in the main building during the whole year. The committee of management states in its report that the water-supply of the asylum is good in quality and sufficient in quantity, that the laying out of airing courts and paths in the grounds is fast approaching completion, and that the sum of £3302 was expended on repairs, additions, alterations, and improvements during the year.

Ennis District Asylum (Report for the year ending March 31st, 1903).—The average number of patients resident during the year was 398, comprising 213 males and 185 females. The admissions during the year amounted to 133—viz., 77 males and 56 females. Of these 74 were first admissions. Mr. Francis O'Mara, the medical superintendent, states in his report that the admissions were 11 in excess of those for the previous year and that the cause of insanity in 30 per cent. of them was due to hereditary predisposition. "In only five cases was intemperance in drink the alleged cause." The number of patients discharged as recovered during the year amounted to 35—viz., 20 males and 15 females, or 8·8 per cent. of the average number resident. The deaths during the year amounted to 26, or 6·5 per cent. as calculated on the same basis. Of the deaths one was due to renal disease, two were due to pneumonia, three to epilepsy, four to pleurisy, six to pulmonary and other forms of tuberculosis, and the rest to other causes. The health of the patients throughout the year was fairly good. In the months of November and December an epidemic of influenza occurred and 50 patients were attacked but without fatal results. Plans have been approved of, and prepared for, the extension of the asylum and a scheme for a new water-supply from Ballycoree Lake is under consideration. The Inspector of Lunatics states in his report that the food of the patients was of good quality; that the condition of the asylum on the whole was satisfactory in spite of some unavoidable degree of overcrowding which would, however, be soon relieved; that the patients appeared quiet and contented; and that the medical case-books and registers were well kept. The committee of management states in its report that the average weekly cost of maintenance per patient was 9*s.* 9*d.*, or nearly 6*d.* less than that for the previous year. The amount contributed from private sources in respect of the maintenance of the patients, having regard to the comparative poverty of the asylum district, continues satisfactory. There are now 36 patients on whose behalf such contributions are made and during the financial year a total sum of £477 4*s.* was received from this source.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8521 births and 5469 deaths were registered during the week ending March 26th. The annual rate of mortality in these towns, which had been 18 6, 19·0, and 19·7 per 1000 in the three preceding weeks, declined again last week to 18·7 per 1000. In London the death-rate was 18·4 per 1000, while it averaged 18·8 per 1000 in the 75 large provincial towns. Among these large towns the lowest death-rates were 8·7 in Willesden, 9·4 in Walthamstow, 9 6 in Hornsey, 9·9 in Leyton, 11·8 in Bootle, 11 9 in Croydon, 12·0 in East Ham, and 12·2 in Merthyr Tydfil; while the highest rates were 23·3 in Birmingham and in Burnley, 23 5 in Salford, 24·2 in Plymouth, 24 3 in Manchester, 24·5 in Birkenhead, 24·8 in Warrington, 28 7 in West Bromwich, and 30·0 in Stockton-on-Tees. The 5469 deaths in these towns included 532 which were referred to the principal infectious diseases, against 503, 500, and 539 in the three preceding weeks; of these 532 deaths 200 resulted from whooping-cough, 176 from measles, 51 from diarrhœa, 46 from diphtheria, 32 from scarlet fever, 21 from "fever" (principally enteric), and six from small-pox. No death from any of these diseases was registered last week in Hornsey, Leyton, Hastings, Bournemouth, Ipswich, Burton-on-Trent, or Bootle; among the other large towns the highest death-rates from the principal infectious diseases were recorded in Great Yarmouth, Norwich, Wolverhampton, St. Helens, Manchester, Salford, Burnley, Leeds, West Hartlepool, and

Gateshead. The greatest proportional mortality from measles occurred in Brighton, Norwich, Stockport, St. Helens, Manchester, Salford, Oldham, Burnley, Leeds, Sunderland, and Rhondda; from diphtheria in Great Yarmouth; and from whooping-cough in Wolverhampton, Walsall, Birmingham, Aston Manor, Salford, Burnley, West Hartlepool, and Cardiff. The mortality from scarlet fever, from "fever," and from diarrhœa showed no marked excess in any of the large towns. Of the six fatal cases of small-pox registered last week in these towns, one each belonged to London, West Ham, Nottingham, Birkenhead, South Shields, and Tynemouth. The number of small-pox cases remaining under treatment at the end of last week in the Metropolitan Asylums hospitals was 110, against 41, 54, and 74 at the end of the three preceding weeks; 54 new cases were admitted during the week, against 13, 21, and 26 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 1578, 1601, and 1624 at the end of the three preceding weeks, had declined again to 1585 at the end of last week; 145 new cases were admitted during the week, against 153, 192, and 176 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 371, 414, and 375 in the three preceding weeks, rose again last week to 383 and were 131 above the number in the corresponding period of last year. The causes of 52, or 1·0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Bradford, Newcastle-on-Tyne, Cardiff, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Willesden, Birmingham, Smethwick, Liverpool, Blackburn, Burnley, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21·2, 21·5, and 23·0 per 1000 in the three preceding weeks, declined again to 22·3 per 1000 during the week ending March 26th, but was 3·6 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·6 in Leith and 20·0 in Perth to 28·1 in Dundee and 31·6 in Paisley. The 737 deaths in these towns included 29 which were referred to whooping-cough, 22 to measles, 15 to diarrhœa, seven to small-pox, seven to diphtheria, four to "fever," and two to scarlet fever. In all, 86 deaths resulted from these principal infectious diseases, against 89, 68, and 65 in the three preceding weeks. These 86 deaths were equal to an annual rate of 2·6 per 1000, which was 0·8 per 1000 above the mean death-rate from the same diseases during the week under notice in the 76 large English towns. The fatal cases of whooping-cough, which had been 36, 21, and 24 in the three preceding weeks, further rose to 29, of which nine occurred in Aberdeen, seven in Edinburgh, four in Glasgow, three in Paisley, three in Leith, and two in Greenock. The deaths from measles, which had been 22, 20, and 23 in the three preceding weeks, declined again to 22 during the week ending March 26th, and included 15 in Glasgow, three in Dundee, and three in Greenock. The fatal cases of diarrhœa, which had been 19, 13, and 18 in the three preceding weeks, increased again to 19, of which eight were registered in Glasgow, four in Dundee, and two Greenock. The deaths from small-pox, which had been three, five, and seven in the three preceding weeks, were again seven during the week under notice, and included four in Greenock, two in Glasgow, and one in Leith. The fatal cases of diphtheria, which had been five, four, and three in the three preceding weeks, increased again to seven, of which three occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 155, 156, and 185 in the three preceding weeks, declined again to 165 during the week ending March 26th, but were 65 in excess of the number in the corresponding period of last year. The causes of 24, or more than 3 per cent., of the deaths registered in these eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·4, 28·3, and 27 7 per 1000 in the three preceding weeks, rose again to 30·4 per 1000 during the week ending March 26th. During the past four weeks the death-rate has averaged 28·2 per 1000, the rates during the same period being 18 8 both in London and in Edinburgh. The 221 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 20 over the number in the preceding week and included 14 which were referred to the principal infectious diseases, against 13, 11, and 20 in the three preceding weeks; of these, five resulted from measles, five from whooping-cough, two from diphtheria, one from "fever," and one from diarrhœa, but not any from small-pox or from scarlet fever. These 14 deaths were equal to an annual rate of 1·9 per 1000, the death-rates last week from the principal infectious diseases being 1·7 in London and 1·3 in Edinburgh. The five fatal cases of measles showed a slight increase over the number in the preceding week. The deaths from whooping-cough, which had been ten, six, and 13 in the three preceding weeks, declined again last week to five. Two fatal cases of diphtheria were registered, against one in the preceding week. The 221 deaths in Dublin last week included 43 among children under one year of age and 58 among persons aged 60 years and upwards; the deaths of infants were slightly in excess, while those of elderly persons showed a marked increase over the number in the preceding week. Eight inquest cases and six deaths from violence were registered, and 91, or more than a third, of the deaths occurred in public institutions. The causes of 14, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel O. R. Bartlett, Hounslow, holds himself in readiness for duty at Sierra Leone. Major O. R A. Julian, C.M G., is appointed to the Thames District for duty. Lieutenant-Colonel H. L. E. White joins at Woolwich for duty as recruiting medical officer. Major V. H. W. Davoren is ordered to the Western District for [illegible] Macdonald, A M.R., assumes [illegible] dquarter Staff, Edinburgh, vice [illegible] A.M.R.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major J. G. Saville to be Surgeon-Lieutenant-Colonel (dated March 15th, 1904). Surgeon-Major F. H. [illegible] landers), to be Surgeon-Captain (dated March 26th, 1904).

THE WAR IN THE FAR EAST.

The *Sciet*, a Russian journal, says that in a short time several Roentgen-ray apparatus will be sent forward to the front for use on behalf of the wounded.

According to the *Novoe Vremya*, the government zemstvo (council) of Moscow in allocating funds decided to institute a series of medical supply depots on the route followed by the army and the zemstvos of other governments have decided to assist in the organisation of this service.

Amongst the questions affecting the supply of materials to the hospitals, &c, at the seat of war, says the *Novoe Vremya*, there is that of furnishing good drinking water, which raises the question of a large supply of ice. The executive committee of the Red Cross Society has decided to take measures to supply the hospitals, &c., in Southern Manchuria with ice-making machines. At the same time large provisions of natural ice will be made at various points.

A note in the *Novoe Vremya* says that half of the students at the Women's Medical Institute have expressed their readiness to go to the Far East. It is stated that at this institute over a thousand women are zealously studying in all branches of medical knowledge. The establishment is supported by voluntary contributions and without aid from the Government. The hopes which had been entertained that the Government might be able to lend material aid have naturally now been weakened by the outbreak of war.

The under-mentioned gentlemen have been appointed dental surgeons to the troops from April 1st, 1904, under the conditions already announced: C. D'E. Foubert, L.D.S. R.C.S Irel.; A. Rice, L.D.S. R.C.S Eng.; H. G. H. Cowell, L.D.S. R.C.S. Edin.; H. C. Toone, L D.S. R C.S. Eng.; J. B. Gillies, L.D.S. R.C.S. Eng.; C. W. Randall, L.D.S. R C.S. Eng.; A. F. A. Howe, L.D.S. R.C.S. Eng.; and J. K. Clark, L.D.S R C.S. Eng.

Inspector-General of Hospitals and Fleets (retired) A. B. Messer, honorary physician to His Majesty the King, has been awarded the Greenwich Hospital pension of £100 a year, rendered vacant by the death of Inspector-General William Macleod, C.B.

Lieutenant-Colonel L. A. Waddell, C.I.E., I.M.S, has been appointed Principal Medical Officer and Antiquarian with the Thibetan Mission and escort.

"Audi alteram partem."

NEUROTIC HEREDITY AND CANCER.

To the Editors of THE LANCET.

SIRS,—Although cancer is not especially frequent amongst asylum populations, yet the instances of its occurrence (visible or verified by necropsy) which have come under my notice in asylums have been in cases of hypochondriacal melancholia and imbecility, psychoses in which neurotic heredity is seldom or never absent. In private practice neuropathic conditions in cancerous patients or their near relatives are met with or heard of so frequently in comparison with the apparently direct transmission of cancer that one is impelled to believe that the real hereditary connecting link between the cancer of the parent and that of the offspring is not cancerous but neurotic. Taking in the first place those of my own cases in which the cancer was distinctly visible or tangible and otherwise perceptible (of cervix uteri, pharynx, neck, or tongue), and the diagnosis, moreover, confirmed by other medical men, I find I have notes of six cases in which either the patient or a near relative (son, daughter, father, mother, brother, or sister)—sometimes the patient and several relatives—presented one or more of the following conditions: hysteria, neurasthenia, transitory delusional and hallucinatory attacks, general paralysis (in a male patient's father), eccentricity, weak-mindedness, paraplegia, spastic paraplegia, marked asymmetry, malformation of the ears and other features, opaque nerve fibres, phthisis, or anæmia. Then five other of my cases (gastric, vesical, or renal cancer) presented in themselves or the near relatives eccentricity, delusions of suspicion, extreme timidity, migraine, severe neuralgia, excessive intolerance of pain, strabismus, malformation of the ears, or transverse fissuring with puffiness of the lips.

Straban (quoted by Talbot, "Degeneracy,") gave an account ("Marriage and Disease") of a family of which the father died from gastric cancer at 60 years of age, a paternal uncle cut his throat at 56 years of age, and the mother died from a fit at 54 years of age. There were seven children; of these one died from cancer, one from convulsions in infancy, and three from phthisis, one was epileptic (had been twice in asylums and was married, without issue), whilst only one was sane and fairly healthy. Referring to history one finds illustrious victims of cancer who have been undoubtedly neurotic. Napoleon is an instance in point. Witness his epileptic fits, his window-counting obsession or obsidional impulse, and his intense egoism, not to speak of his "star" and his "familiar" which may have been mere clap-trap. Other illustrious personages who have died from cancer have had relatives eccentric, epileptic, suicidal, paralytic, or periodically insane.

Let us now reverse the process and look from the neurotic subject to the cancerous relatives. A young adult female patient of mine who suffered from severe though curable chorea was descended from grandparents two of whom (the maternal) died from cancer; her mother is neurotic, eccentric, and the subject of chronic eczema, and her maternal aunt has had a cancerous breast removed. Two female patients suffering from dementia præcox sprang from a grandfather who died from gastric cancer at the age of 60 years, whose brother and sister died at a later age from senile dementia, and of whose sons one was a ne'er-do-well, three were alcoholic (two of whom died from phthisis), and one was kyphotic. A female patient, aged 62 years, who has nearly all her life suffered intensely from symptoms which she prefers to call "nerves"—viz., pains and paræsthesiæ of all sorts, with fancies that she is affected with any fatal disease of which she hears, so that in some of her periodical exacerbations her condition has bordered on agitated melancholia—had a brother who died from cancer of the throat. Her daughter and sons are distinctly neurotic and eccentric. Her daughter has four children, each of whom is, or has been, affected with one or more of the following—viz., chorea, convulsions, nystagmus, chorea major, flightiness, unruliness, dwarfism, congenital cataract, aural and ocular malformations, dorsal hairiness, psoriasis, molluscum, and rickets.

Talbot ("Degeneracy") quotes from Kiernan[1] a description of a degenerate family of which the following are some of the items. The progeny of a nymphomaniac and her strabismic migrainous cousin were a ne'er-do-well, a periodical lunatic, a dipsomaniacal daughter who died from gastric cancer, deformed triplets who died at birth, an epileptic imbecile son, a hermaphrodite, a prostitute, a double monster born dead, a normal daughter, and a paranoiac son. The progeny of a female sexual invert and her cousin, a versifier, soon divorced, were a daughter with periodical nymphomania, who had some artistic and literary ability, and a son who died from gastric cancer. The progeny of a normal woman and her ataxic husband were a dead-born sarcomatous son, a gouty son, twin boys paralysed in infancy, twin girls normal, a normal son, and a son ataxic at 14 years of age.

As collateral evidences may be adduced: 1. The marked relationship between the presence of nerves and the spread and limitation of cancer in the skin and muscles, as shown by Mr. G. Lenthal Cheatle[2] (The common origin of the epidermis and the great nervous centres from the epiblast is worth bearing in mind in this connexion.) 2. The fact observed by Mr. D'Arcy Power[3] that after operation recurrence is diminished in frequency and postponed by change of scene and surroundings, which is well known to be a useful measure in the treatment of diseases of the nervous system. 3. The beneficial action of radium on some malignant and certain nervous diseases.[4] 4. The simultaneous increase of cancer and functional nervous diseases in civilised communities. 5. The markedly greater incidence of cancer in certain urban (Australian metropolitan) than in the surrounding rural districts.[5] (Syphilis, alcoholism, and tuberculosis are much more probably co-results with cancer of urban life than causes of the disease.) 6. The rarity of cancer as well as of nervous diseases amongst savages.

It may be objected that animals suffer from cancer. But are they not also subject—at all events, those of which we know most—to chorea, convulsions, paralysis, and hydrophobia? The observations here submitted are too few to be conclusive, but I think they are sufficiently numerous and relevant to warrant investigation in this direction. Those who are best fitted to offer evidence on the point are private practitioners who actually *know* the patients and their near relatives. Should it be proved conclusively that the neurotic—not necessarily the degenerate—constitution is a predisponent of cancer it hardly needs saying that the knowledge of this relationship would be of great service in the diagnosis of the early stages and perhaps to some extent even in the prophylaxis of that disease.

I am, Sirs, your faithfully,

Liverpool, March 16th, 1904. JAMES SHAW, M.D. R.U.I.

PS.—That cancer is, or appears to be, most common in districts which are very well watered and wooded is by no means an insuperable bar to the acceptance of the view that neurotic heredity is the chief predisposing cause of the disease. Such districts must naturally include deep secluded valleys where insalubrious climatic conditions and the custom of intermarrying closely tend to accentuate and to perpetuate any original neurotic taint.—J. S.

PARTIAL RESECTION OF THE ASTRAGALUS FOR TALIPES VARUS.

To the Editors of THE LANCET.

SIRS,—I am not aware if the undermentioned simple modification of Lund's operation for talipes varus has been tried before. In September, 1902, I was asked to see a boy, aged eight years, who since the age of three years had been unable to walk (even to school) I found a typical case of talipes varus. The lad was placed under chloroform by my assistant and after tenotomy of the tibialis anticus and posticus I made an incision through the skin over the dislocated portion of the astragalus and drawing the tissues on each side I removed a wedge-shaped piece of this bone as large as possible but leaving the articular surfaces (the apex being downwards). After tenotomy of the tendo Achillis I dressed the wound and put on a splint of my own construction. The plantar fascia I left intact as I considered in so young a subject that it would stretch. The wound healed rapidly. The boy used a pair of Messrs. Down Bros.' boots until they wore out, since when he has used ordinary ones. He can now run about without trouble. I would draw your notice to the following points: (*a*) the ease with which the operation was done in a cottage, taking less than 30 minutes; (*b*) the fact of it being practically bloodless; and (*c*) the deep restraining ligaments being apparently reached without difficulty. I have not had an opportunity of performing this operation again but thought perhaps that someone more fortunately situated might like to try it.—I am, Sirs, yours faithfully,

---

PREVENTION OF INFECTIOUS DISEASE IN BATH.

To the Editors of The Lancet.

Sirs,—In his letter in your issue of March 26th, p. 896, Dr. Preston King has shifted somewhat from the very decided position he took up in his previous communication, inasmuch as he now admits that if Section 126 of the Public Health Act, 1875, be taken alone my contentions are quite right.

It was his definite statement to which I chiefly took exception, because I was satisfied he could not support it by *any section of any Act of Parliament.* I know that many others share his opinion in this matter, but I entirely disagree with this view of the question and as the point involved seems to me to be an important one I will give a few of the reasons upon which I base the opinion I hold. In the first place I will point out that the word "dangerous" does not appear in the Notification Act. Had this been so Dr. King's case would have been a much stronger one, but the absence of that important word, in my opinion, materially weakens his argument. Again, the objects of Section 126 and the Notification Act are not altogether similar. The sole purpose of Section 126 is to prevent the spread of dangerous infectious disorders, whereas the primary object of the Notification Act is to provide *for* the notification of infectious disease to local authorities. Of course, I am aware that its ultimate object is the prevention of the spread of infectious diseases. The Notification Act gives power to local authorities to make diseases notifiable for temporary periods. This has been frequently taken advantage of in the case of chicken-pox. Now chicken-pox is not scheduled because it is a dangerous infectious disorder but because it very much resembles mild and *modified forms of small-pox. It is simply done* to obtain information and to enable the authority to investigate these cases and to secure as far as possible the notification of all cases of small-pox.

Does a step of this kind on the part of a sanitary authority

Act was adopted or not and according to whether other diseases than those mentioned in the Act were included therein. Surely it cannot be argued that an adoptive Act could define and modify in a district in which it was not in force an important section of the Public Health Act, which Act is the foundation of the whole sanitary administration of the country. In 1899 the Notification Act was made compulsory throughout the country except in Huddersfield. This Act not being in force in Huddersfield, has Section 126 a different application in that borough?

It seems to me most unlikely that erysipelas can be held to be a dangerous infectious disorder and the so-called puerperal fever is only dangerous and infectious to lying in women. It is neither dangerous nor infectious so far as the general public are concerned. Consequently if Section 126
applies at all to this disc
very partial and limited cha
legislature included in the
not dangerous infectious d
term and did not include therein diseases that admittedly bear those characteristics, how can it be held with any weight of reason or force of argument that Parliament intended the Notification Act to define, to modify, and to limit the application of Section 126 of the Public Health Act? The vagueness is in the assumption that Parliament intended this rather than in the meaning of the term "dangerous infectious disorder."

I am, Sirs, yours faithfully,
J. T. Neech.
Halifax, March 28th, 1904.

SYPHONAGE AND HYDRAULIC PRESSURE IN THE LARGE INTESTINE.

To the Editors of The Lancet.

Sirs,—I gather from Dr. Keith's remarks in a recent number of The Lancet that he has seen only the brief account given in the reprint, with notes, of my article in the *Edinburgh Medical Journal*, but much additional evidence will be found in my book (Churchill). A large part of Dr. Keith's criticism is directed against the existence of tonicity in the longitudinal bands, but all of this falls to the ground, for the fact has been confirmed by actual observation. I used glass tubes in most of my experiments because I wanted to see what was going on, but I obtained precisely the same results with a length of old garden hose, bent to imitate the flexures of the colon, and I contend that the concertina like shortening of the bowel and other by-effects of the tonic contraction would give a rigidity at least equal to this. Moreover, I pointed to many clinical and other phenomena which are perfectly explained by the syphon hypothesis and by no other.

Arguments drawn from observations in animals have but little bearing upon the case, for the simple reason that the colon is horizontal. Were this the case in man peristalsis, though handicapped by the presence of saccules and the absence of any true circular fibres, would probably suffice. To take a case of orthopnœa, of perhaps years' duration, how can peristalsis of a large-bored and feeble ascending colon suffice alone to propel the intestinal contents? Dr. Keith also seems to question my point that the ileo-cæco-colon is constructed on hydraulic lines, but surely this is indisputable and has only to be pointed out to be at once recognised. It has, at any rate, the endorsement of a large number of physicists with whom I have been in communication.

I am, Sirs, yours faithfully,
R. W. Leftwich.
March 26th, 1904.

A DISCLAIMER AND PROTEST.

To the Editors of The Lancet.

Sirs,—I have just received by post a book entitled "*Fruitless Experiment*," edited by Stephen Smith, M.R.C.S., and published by the London Anti-Vivisection Society, in which my name appears as a contributor. I should esteem it a favour if you would allow me to state that the article in question is published without my knowledge or consent and that I strongly object to the unauthorised use of my name and work in this connexion.

I am, Sirs, yours faithfully,
William Murrell.
Welbeck-street, W., March 28th, 1904.

THE INSTITUTE OF MEDICAL SCIENCES APPEAL AND SIR DONALD CURRIE'S GIFT.

To the Editors of The Lancet.

Sirs,—Your leading article of last week, commenting on the munificent gift of Sir Donald Currie to the school of advanced medical studies about to be formed in connexion with University College Hospital contains the following: "It is possible that Sir Donald Currie's gift will indirectly postpone the completion of the scheme of building new laboratories at South Kensington."

We hope and believe that, on the contrary, it will, by drawing attention to the needs of the University and its medical faculty, stimulate other donors to come forward and thus enable the Senate, now that the success of the scheme for the incorporation of University College is so nearly assured, to carry through the second important proposal which it has put forward—viz., the founding of an institute of medical sciences at South Kensington, the necessity for which is in no way affected by Sir Donald Currie's gift. A large sum is still required for this purpose and donations will be gratefully acknowledged by

Yours faithfully,
J. K. FOWLER, } Honorary treasurers, Institute
H. T. BUTLIN, } of Medical Sciences Fund.

35, Clarges-street, W., March 29th, 1904.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic: Continued Rise in Mortality.

THERE has been a steady increase in the number of deaths from plague throughout India during the past three weeks and the weekly total is approaching 30,000. The principal increases are in the Punjab and the Bombay Presidency but the disease is raging in the United Provinces and is developing in Kashmir. Bombay city records about 100 deaths a day and the recrudescence is rapidly developing in Calcutta. Karachi city is again very severely attacked and compared with other places the outbreak is widespread and virulent. Both Calcutta and Bombay city seem to show this year a lateness in the annual recrudescence, but while this recurrence in Calcutta has been hitherto very regular in season there has been a tendency to develop later each year in Bombay. In Karachi the outbreaks have generally developed in the teeth of the hot weather. Although there is no reported plague in Madras city the general mortality is very high (45·7 per 1000) and there is no epidemic of cholera or small-pox to account for it. The ten years mean is 34 9. The first division of the city shows a death-rate of 50 per 1000. The sanitary administration of this city is behind the times and the commissioners have recently declined to allow the health officer to meet those of Bombay and Calcutta for consultation upon an improved system of death returns. There is no municipal laboratory in Madras city, which is put down to poverty but which can only be explained by indifference in sanitary matters.

The health officer's report for Bombay during the last quarter of 1903 shows a death-rate of 36·76 per 1000, notwithstanding that plague was much less than in the corresponding week of the previous year. The municipal dispensaries seem to be working well. The registration of births and the vaccination of infants seem to be very defective in Bombay but in this respect Calcutta is just as bad, if not worse.

March 10th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Diploma in Public Health at the University of Liverpool.

THE University of Liverpool has enlarged its sphere of usefulness by the institution of a diploma in public health. The diploma will be awarded only to candidates who shall have passed the prescribed examination and before entering for any part of it they must have held for not less than 12 months a registrable qualification in medicine, surgery, and midwifery. They must also present satisfactory certificates of having attended approvedcourses of study. The examination for the diploma will be held once yearly, at the end of the summer term. The first examination will take place at the end of the summer term, 1904. The examination will be conducted in two parts and candidates may present themselves in Parts I. and II. separately or at the same time, provided that no candidate will be admitted to Part II. unless he shall have satisfied the examiners in Part I. No candidate's name will be published until he has been successful in both examinations. Prior to admission to the examination he must have presented satisfactory evidence (1) of having attended, during at least three months, an approved course of instruction in public health at the University; (2) of having attended (after obtaining a registrable qualification) during at least six months practical instruction in the laboratories of the University in chemistry as applied to public health, bacteriology, and the pathology of those diseases of animals which are communicable to man; (3) of having attended during not less than three months (after obtaining a registrable qualification) the clinical practice of an approved hospital for infectious diseases; (4) of having (after obtaining a registrable qualification) during six months (of which at least three months shall have been distinct and separate from the period of laboratory instruction required under 2) been diligently engaged in acquiring a knowledge of the duties, routine and special, of public health administration under the supervision of a medical officer of health who is also a teacher in the department of public health of a recognised medical school; or (1), in England and Wales, the medical officer of health of a county, or of a single sanitary district having a population of not less than 50,000, or a medical officer of health devoting his whole time to public health work; or (2), in Scotland, a medical officer of health of a county or counties or of one or more sanitary districts having a population of not less than 30,000; or (3) in Ireland, a medical superintendent officer of health of a district or districts having a population of not less than 30,000. The subjects of examination in Part I. shall comprise chemistry, microscopy, physics, and engineering, all as applied to public health, together with practical pathology and bacteriology. Part II. will include the etiology of disease, sanitary law and administration, vital statistics, sanitary reporting, and practical examination in infectious diseases. The fee for the examination for the diploma shall be £5 5*s*.

University of Liverpool: First Degree Ceremony.

The University of Liverpool conferred its first degrees on March 25th; the occasion was one not merely of interest but also opened a new chapter in the academic record of the city. In the absence of the Chancellor (the Earl of Derby, K.G.) the ceremony was performed by the Vice-Chancellor (Principal A. W. W. Dale). The degrees conferred were those of bachelor of medicine and bachelor of surgery, the recipients of which were Mr. Stanley Brown, Mr. William E. Cooke, Mr. Arthur Hendry, and Mr. Herbert R. Hurter. The Vice-Chancellor, addressing the new graduates, said they would stand first on the roll that now opened. Their names would head a list which the years as they passed would lengthen. But even now they would not stand alone for any length of time, for the University had extended an invitation of incorporation to graduates of the Victoria University of Manchester who received their teaching and training in Liverpool and the manner in which that invitation had been accepted was enough to prove its wisdom. Already more than 300 applications for incorporation had come in and almost every post was adding to the number. Until those letters reached him he had hardly realised how much work the old college had done, how much its influence had spread, and to what remote continents and under what strange skies. The four graduates were presented by the Dean of the medical faculty (Professor B. Moore) to the Vice-Chancellor who, in formally admitting them, said: "By virtue of the authority vested in me I admit you to the degrees of bachelor of medicine and bachelor of surgery." The ceremony took place in the Senate room of the University.

Liverpool Chamber of Commerce: Appointment for Professor R. W. Boyce, F.R.S.

At a meeting of the committee of the African trade section of the Liverpool Chamber of Commerce held on March 16th it was resolved, on the motion of Sir Alfred Jones, K.C M.G. (the chairman of the section), that Professor Rubert W. Boyce of the University of Liverpool and Dean of the Liverpool School of Tropical Medicine should be appointed as a special advisory member of the committee in matters relating to health and sanitation. Professor Boyce had taken a great interest in the sanitation of the West Coast of Africa and his appointment as a special member of the African trade section of the Chamber of Commerce is recognised as a fitting tribute to his energies in that direction.

Presentation to Dr. Thomas Clarke, J.P.

An interesting ceremony took place at the town-hall on March 23rd, the occasion being a presentation to ex-Alderman

Dr. Thomas Clarke from his former colleagues of the city council, from which body he retired in November of last year. The Lord Mayor, who was accompanied by the Lady Mayoress, made the presentation which consisted of a richly chased silver Georgian tea and coffee service and salver and on the latter was engraved the following inscription: "Presented to Alderman Thomas Clarke, J.P., from his colleagues in the city council as a mark of their high esteem and personal regard upon the occasion of his retirement. November, 1903" Dr. Clarke was a member of the city council for 11 years and during that time he occupied the chairmanship of the hospitals committee. When he began his work in connexion therewith the accommodation in the city hospitals was limited to about 350 beds, now there was accommodation for close on 1000 patients. Dr. Clarke, in returning thanks for the gift, said the advance which had been made in the manner in which cases of infectious disease were treated by public bodies was very remarkable and that Liverpool was now, or shortly would be, in a position to meet all possible requirements and would take a very high place among the cities of the Empire in regard to the ample accommodation provided for dealing with those diseases.

Health Committee and Vaccination.

The health committee of the city council passed a resolution on March 17th informing the Local Government Board of its approval of the Revaccination Bill now before Parliament and requesting the Board to do all in its power to secure its becoming law.

Cheshire Hospital Scheme.

The joint Mid-Cheshire hospital authority decided to apply to the Local Government Board for power to borrow £14,500 for the erection of an isolation hospital for Northwich rural and Northwich, Winsford, and Middlewich urban districts. The entire scheme is estimated to cost about £16 000, one-third of which will be borne by the Cheshire County Council. The authority is the first joint hospital committee created under an order in Cheshire.

March 28th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Health Report of the Sanitary Authority of the Port of Cardiff.

Dr. Edward Walford, the medical officer of health of the Cardiff Port sanitary authority, has just issued his annual report and a perusal of its pages reveals the indebtedness not only of Cardiff but of the adjacent districts to the sanitary staff of the authority, for it is due to its vigilance that cases of infectious disease upon incoming vessels are detained at the port of Cardiff. During 1903 five cases of small-pox, 12 of typhoid fever, and one of diphtheria were thus detained and treated in the Cardiff borough isolation hospital. No cases of plague or of cholera were brought into Cardiff, although 20 vessels entered the port from places which were either infected, or suspected of being infected, with plague, and the medical officer of health examined in accordance with the Local Government Board regulations 513 persons on the suspected ships. In connexion with these 20 vessels the rat-catchers employed by the port sanitary authority destroyed 1405 rats, either in traps or by sulphurous acid gas, the carcasses being burned. Cardiff is well provided with an isolation hospital, situated on Flat Holme Island, in the middle of the Bristol Channel, for cholera, yellow fever, or plague patients. There is accommodation for 16 patients in three wards and there is ample room on the island for the erection of tents or huts A crematorium is attached for the destruction by burning of the bodies of persons dying in the hospital. The institution belongs to, and is administered by, the Cardiff authority but the Bristol authority has the use of the crematorium while the Barry and Newport authorities pay an annual sum of £40 and the Bridgwater authority pays an annual sum of £20, in return for which patients are received from the three districts named and charges are made of three guineas a week for the first patient received and two guineas a week for every additional patient and a further sum of seven guineas in respect of the cremation of the body of any of these patients who die in the hospital. Of the 11,674 vessels which entered the port during 1903 no fewer than 8072 were inspected by Dr. Walford's staff of six inspectors and 1228 had one or more sanitary defects. Dr. Walford states that shipowners and masters willingly carry out the recommendations of the port sanitary authority, with the result that the proportion of vessels having sanitary defects amongst those which frequent the port of Cardiff has decreased in a very marked degree. The Cardiff and county public health laboratory rendered useful aid in examining bacteriologically the drinking-water from 66 vessels. In 46 instances the samples were found to be impure.

New Workhouse at Newport.

The new workhouse which has been erected by the Newport (Mon.) board of guardians was formally opened on March 26th. The population of the Newport union is approaching 120,000 and the accommodation provided in the new buildings is for 600 inmates. The total cost is £58,900, a sum considerably in excess of the original estimate of £37,000 made four years ago. The ten blocks for the inmates include four for men, four for women, one for eight married couples, and one for infants. Each of these blocks has a separate yard and garden. There are telephones between the principal blocks and most of the buildings are lighted by electricity.

Vagrancy in Monmouthshire.

The Monmouth board of guardians has been making successful efforts to deal with the large number of able bodied tramps who pass through the county. Permission was obtained last year from the Local Government Board to increase the task of stone breaking from four to six hundredweights and it was decided that every tramp who refused to complete his task should be dealt with by the justices. During the past six months an average of six men monthly have been imprisoned for periods varying from 14 days to one month and a marked diminution in the number of tramps calling at the workhouse has taken place. In the first quarter of 1903 the number was 1073, but during the same period of the present year it was only 577.

Keynsham Rural District Health Report.

Mr. J. O. Heaven, the medical officer of health of the Keynsham rural district, which lies between Bristol and Bath, reports a death-rate of 9 52 per 1000 among a population of 8507 persons during 1903. This is lower than any death rate recorded in the district during the past ten years. There was only one death from infectious disease during the year, the case being one of scarlet fever.

March 28th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

University of Glasgow: New Appointment.

THE Glasgow University Court has at a recent meeting appointed Mr. Frederick Soddy, M A. Oxon., lecturer on physical chemistry for five years, the appointment to date from Oct. 1st next. Mr. Soddy is well known for his work in radio-activity which he conducted in association with Professor Rutherford at McGill College, Montreal At present he is engaged with Sir William Ramsay, K.C.B., LL.D., at University College, London, in a research on the gases produced by radium.

Commemoration Day at the University of Glasgow.

Arrangements are now practically completed for the celebration of the first commemoration day of the University of Glasgow. The date is fixed for Tuesday, April 19th, which is also graduation day In the forenoon a Divine service will be held in the Bute Hall, which will be followed by an oration by Sir William Ramsay, of University College, London, on Joseph Black, the lecturer in the old College on chemistry from 1756 to 1766 and the enunciator of the doctrine of latent heat. There is a peculiar fitness in Sir William Ramsay delivering this oration as he himself began his brilliant career in chemistry as one of the teaching staff at Gilmorehill. At the graduation ceremony which is to follow the oration Sir William Ramsay, among others, is to receive the honorary degree of doctor of laws. In the evening a banquet is to be held in the Bute Hall, at which Sir William Ramsay will be entertained as the guest of the evening. This banquet is open to graduates and other members of the University. As there will be a great number of applications for tickets these will be balloted for a few days before the banquet.

Closing of the Winter Session at Glasgow.

The closing of the winter session of the University, Anderson's College Medical School, and St. Mungo's College took place on March 24th. At Anderson's College the medals, prizes, and certificates were presented by Lady Primrose, who was accompanied by the Hon. the Lord Provost (Sir John Ure Primrose, Bart.), while at St. Mungo's College a similar duty was performed by Mr. Hugh Brown, president of the governors.

University of St. Andrews.

At the annual ceremonial of graduation, held on March 29th, the degree of LL.D. was conferred (*honoris causâ*) on Sir Charles Gage Brown, K.C.M.G., M.D.

March 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Poor-law Medical Service.

THE *Irish Times* has always shown itself a friend to the Irish Poor-law Medical Service and has pressed forward its claims and referred to its grievances again and again. THE LANCET has for years been in sympathy with the underpaid medical officers who take care of the poor in Ireland. The *Irish Times* of March 28th contains a leading article in which it is reiterated that so far the dispensary and workhouse medical officers have cried aloud in the wilderness without effect and that between the Local Government Board on the one hand and the local boards of guardians on the other the grievances of the Poor-law medical officers of Ireland remain unredressed. A special commissioner from the *British Medical Journal* has recently visited Ireland and in his report, after specifying the notorious grievances of this service, which have appeared in print elsewhere for years, makes the following bold and somewhat revolutionary suggestion. He advises the creation of the post of director-general of the State medical service in Ireland who would have under him four provincial inspectors-general and 20 county inspectors; that the workhouse infirmary service and the dispensary service should be amalgamated; and that the medical officer should, after a certain date, enter the service by competition. These proposals, however much their realisation might be desirable, are not, it occurs to me, likely to lead to any practical result. The Irish Medical Association has failed to obtain any redress of the grievances of the Poor-law medical officer as regards frequently inadequate salary, holiday leave, sick leave, and fixed salary or superannuation. Nobody has doubted the justice of these claims. It seems impossible to do so, but the local boards of guardians have such matters practically in their hands and much injustice results. The Local Government Board of Ireland has really done nothing for the oppressed medical officers although it is a State service and under State control. The Irish Medical Association has not succeeded in doing anything although it can influence many Members of Parliament. Unfortunately its own members seem "more Hibernico" at variance and the necessary pressure has not been exerted.

Royal Victoria Hospital, Belfast.

At the annual meeting of the friends of this charity, which was held on March 22nd, Mrs. W. J. Pirrie being in the chair, a very satisfactory report was received from the construction committee. The gross total for the building fund was £108,994 and the expenditure was £125,961, leaving a deficiency of £16,967. A portion of this was paid by Mr. and Mrs. Pirrie as the work progressed and they also gave a large sum towards the furnishing. At the last meeting of the construction committee it was found, however, that there was still a debit balance of about £11,000, which Mr. Pirrie, in the most generous way, said that he and his wife would make good. This magnificent generosity of Mr. Pirrie has relieved the construction committee from a great responsibility. A very hearty and cordial vote of thanks, on the motion of the chairman of the board of management (Mr. W. Crawford, J.P.), seconded by the President of Queen's College, and supported on behalf of the medical staff by Professor J. W. Byers, was then passed to Mr. and Mrs. Pirrie. It is to their untiring industry and unselfish devotion that there is now such a complete hospital in Belfast, so advantageous for the sick and so valuable for the clinical school. In addition to their own noble gifts (upwards of £20,000), and the trouble and the time spent in collecting £100,000 for building and £50,000 as an endowment fund, Mr. and Mrs. Pirrie have during the past seven years laboured ungrudgingly in the general furtherance of the scheme. In her speech, when moving the adoption of the annual report, Mrs. Pirrie urged the claims of the hospital for further support so that all the beds might be utilised.

Ulster Hospital for Women and Children.

At the annual meeting of the friends of this charity on March 25th it was reported that 221 children in the wards and 1859 in the out-patient department were treated, while in the women's department there were 84 intern and 373 extern cases. There were four intern maternity and 147 extern labour cases. All the debt on the hospital has been wiped out and there is a balance at the bank of £527.

Ulster Medical Society.

The seventh general meeting of this society was held in the physiological laboratory of Queen's College on March 24th, Dr. J. Campbell, the President, being in the chair. Professor T. H. Milroy gave a microscopic demonstration of Ascending Degeneration in the Spinal Cord after Section of the Posterior Sacral Roots. He also showed a Method of Demonstrating the Action of Drugs upon the Blood-pressure and upon the Volume of Organs. Dr. J. A. Milroy read a paper on Some Products of the Action of Reducing Agents upon Blood Pigment. Professor J. L. Smith read a paper on the Infectivity of Typhoid Fever. Pathological specimens were also shown by various members of the society.

Death of Mr. James Stuart, M.D. R.U.I.

Dr. James Stuart of Ballymena died from pulmonary tuberculosis on March 23rd in London, at the residence of his friend, Dr. John Simpson, in Carleton-road, Tufnell-park, N. Dr. Stuart studied at Queen's College, Belfast, and graduated as M.D. of the Queen's University in 1877. He afterwards settled in Ballymena where, by his skill, kindly nature, and extreme attention to work, he developed a very large practice. He was buried in the New Cemetery, Ballymena, in the presence of an immense number of sorrowing friends.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Motorists' Fractures.

AT the meeting of the Academy of Medicine which was held on March 15th M. Lucas-Championnière gave an account of fractures which are peculiar to those who deal with motorcars. Fracture of the forearm, for instance, is particularly common. It is produced in the following way. When the handle of the starting gear is turned in the ordinary manner a "back fire" is wont to occur and so the handle is violently reversed. The main cause of this accident is that the chauffeur has omitted to retard the sparking before turning the handle of the starting gear. If the chauffeur holds the handle of the starting gear too tightly so that he has no time to disengage the pawl which connects it with the axle of the motor he may fracture his radius by tearing (*arrachement*). If, however, he holds it lightly and stops turning at the proper moment he can throw it out of gear by a simple turn of the wrist. There are also cases on record where the handle even when left to itself reverses suddenly and comes into violent contact with the arm causing a fracture by direct violence. The leg may also be fractured in the same way. As a rule the fractures in question are caused by *arrachement*, but some are due to direct violence. M. Lucas-Championnière has studied with great care the mechanism of these fractures. According to him the *arrachement* is due to the sudden reversal of the wrist and a violent strain on the ligaments connecting the hand with the lower end of the radius. All these fractures heal well under gentle movement and massage. The paper was illustrated by three radiographs.

Honours to Professor Cornil.

The friends and pupils of Professor Cornil have taken the triple occasion of his resignation as physician to the hospitals, of his scientific jubilee, and of his promotion to the rank of officer in the Legion of Honour to give him a gold medal designed and executed by the sculptor, M Pillet The medal bears a head of Professor Cornil on the obverse and on the reverse the graceful figure of a woman as symbolising science while in the background appears the elevation of the Hôtel Dieu The 200 subscribers to the medal met for a banquet at the Grand Hotel on March 8th, Professor Debove, Dean of the Faculty of Medicine being in the chair One after another the President and such well known men of science as Franck Chauveau, Bar, Berger, Blondel Chaumat, Léon Labbé, and others spoke in honour of their master whose reply was couched in words at once dignified and touching in their simplicity There is no need to give a detailed description of Professor Cornil s work to the readers of THE LANCET All the world knows that to him is due the renaissance in France of pathological histology Thanks to him this branch of science has become one of the glories of French medicine Professor Cornil it was too who organised and handed over to his pupil Professor Chantemesse the principal French bacteriological laboratory, exclusive of the Pasteur Institute In collaboration with M Ranvier he has written many excellent treatises on medicine and during the 20 years that he has sat in the Senate he has been the cause of the passing of the most important Acts dealing with hygiene, the Assistance Publique, and higher education

The National Periodic Congress of Gynæcology, Obstetrics, and Pediatrics

The fourth session of the above named congress will meet at Rouen from April 5th to 10th The president is M Richelot, *agrégé* professor at the faculty, surgeon to the Paris hospitals and member of the Academy of Medicine M Richelot will also be president of the gynæcological section, while the section of obstetrics will be presided over by M Guillemet, professor in the Nantes School of Medicine, and that of pediatrics by M Kirmisson, member of the Academy of Medicine Nine chief subjects are put down for discussion Any medical man, Government or other official (*administrateur*) philanthropist student in medicine, or midwife may attend the congress Names and subscriptions should be sent to Dr Albert Martin, professor at the Rouen School of Medicine

A New Professor

Dr Paul Reclus, an *agrégé* professor, surgeon to the hospitals, and member of the Academy of Medicine, has just been appointed to the chair of operative surgery and surgical apparatus Dr Reclus, who was born in 1847, was *externe* to the Paris hospitals in 1868, in 1871 he won a medal and was appointed *interne* In 1875 he won the gold medal and in 1876 was appointed anatomical assistant at the faculty and took his doctor s degree He won the silver medal for his thesis In 1877 he was appointed prosector, in 1879 surgeon to the hospitals coming out first among the competitors, and in 1880 he was made *agrege* He was laureate of the academy in 1878 and in 1882 won the Godard prize at the institute for his work on syphilis of the testicle In 1895 he was elected a member of the Academy of Medicine Among the many lectures which he has delivered are the free course in clinical surgery delivered at the Broussais the Pitié and the Laennec Hospitals, to the last of which he is attached He has published many important books and papers and his name will be always connected with cystic disease of the breast and with an operation for the establishment of an artificial anus in the iliac region

False Reports as to a Typhoid Fever Epidemic in Paris

The political journals have begun a campaign against the water supply of Paris which is apparently inspired by the personal feeling of certain prominent hygienists against the Director of Public Hygiene and also by some financiers who wish to influence public opinion and the Government in favour of a scheme for supplying Paris with water from the Swiss lakes So at least says the rumour and I give it without assuming any responsibility for it Its existence however, will explain the evident desire to produce a panic As a matter of fact the number of cases of typhoid fever in Paris is barely above the normal for this season of the year Last year the number was 11 per 100 000 while this year the proportion is 14 The total number of cases at present under treatment is 300 20 years ago the proportion of typhoid fever cases was 123 per 100 000

BERLIN

(FROM OUR OWN CORRESPONDENT)

Defective School Children

SOME years ago the Berlin school authorities arranged that children who were found to be in some degree defective, though not unable to attend school, should receive instruction in special classes in connexion with the municipal schools All children are regularly examined by the medical officers of the schools and in accordance with their advice the defective ones are selected for the special classes Up to the present time 1300 children have been removed from the ordinary classes, being 0 6 per cent of all the pupils of the Berlin municipal schools According to statistical returns 1 per cent of the children in Germany are defective, so that there probably are still about 0 4 per cent in Berlin whose abnormal condition has not been recognised on examination According to a paper read by Dr Nauratzky before the Berlin Society for School Hygiene the parents as well as the teachers often fail to realise a child's condition mistakes attributed to laziness or to stupidity being often in reality a symptom of defective intelligence As to the causes of the defective state in question Dr Nauratzky found that in about 60 per cent it was due to heredity, especially to alcoholism on the part of the father or mother In about 30 per cent the social condition of the child s family had an influence , among the very poor habitual insufficiency of food interfered with the normal function of the brain The third group included children who had suffered from some exhausting illness before the third year of life. The first group of children was always, and the third group was nearly always, incurable, whilst in the second group the mental functions might return to the normal standard if the child was well fed and well cared for Symptoms of mental defect which ought to be recognised by the teachers were partly intellectual, such as bad memory and slowness of comprehension and were partly moral Children who neither by punishment nor by persuasion can be deterred from habitual untruthfulness, from playing truant, and from infractions of school discipline must always be suspected of mental defect

Medical Qualifications in Germany

According to the official gazette (*Reichsanzeiger*) 1562 medical men became legally qualified during the year 1903—a number considerably greater than during either of the two preceding years in each of which respectively the numbers that passed the State examination were 1432 and 1344 The highest number ever attained was in 1891 when 1570 candidates passed—only eight more than became qualified in 1903 Owing to the overcrowding of the profession it is some consolation to learn that the number of medical students shows a regular though slight decrease during the last few years The number of dental qualifications in 1903 was 162 as in the preceding year

The Antivaccination Movement

The antivaccination movement is as strong in Germany as in England, although the law with respect to compulsory vaccination is much stricter in the former country A journal which denounces vaccination recently asserted that in defiance of the law the children belonging to the Imperial family had never been vaccinated In order to ascertain whether this rumour had any foundation the *Zeitschrift fur Arztliche Fortbildung* applied to Dr von Leuthold, the Emperor s physician in ordinary, who in reply wrote that he was authorised by His Majesty to send the editor a copy of [illegible] by Dr Zunker, the physician [illegible] the successful vaccination [illegible] y s children are certified in accordance with the law

March 29th

QUEEN CHARLOTTE'S HOSPITAL —A grand morning concert in aid of Queen Charlotte s Hospital, Marylebone road, of which Her Majesty Queen Alexandra is patron and the Princess of Wales is vice patron will take place at the Queen s Hall Langham place London, W on Thursday, May 5th at 3 o clock Madame Melba who has kindly consented to sing on this occasion is arranging the programme Tickets £1 1*s* 10*s* 6*d* , and 5*s* , may be obtained from the Social Bureau 30 New Bond street, London, W , and from the secretary of the hospital

Obituary.

DEPUTY SURGEON-GENERAL HENRY CAYLEY, C.M.G., F.R.C S. ENG., I.M.S., A.K.C.,

HONORARY SURGEON TO THE KING.

THE announcement of the death of Deputy Surgeon-General Cayley in last week's papers came as a shock to most of those who were included in his large circle of friends, for it was most unexpected even by many of those who knew him best. Of a spare build, addicted to the joys of the saddle, shooting, and golf, and to most field sports, he led a temperate life which might have been expected to be prolonged for many years. His fatal illness is reported to have been the result of a fall from his horse while on active service in South Africa, on the occasion of which he fractured several ribs and received other injuries. He passed away at Leavesden, Weybridge—to which beautiful neighbourhood he retired on vacating his appointment at Netley—on March 19th in the seventieth year of his age. He was buried at Weybridge cemetery on March 23rd.

Henry Cayley was a scion of the old family of Cayley which was settled at Owby in the thirteenth century, a member of which subsequently purchased the estate of Brompton in Yorkshire and there resided in early Stuart times. His ancestor, Sir William Cayley of Brompton, was knighted by Charles I. and was created a baronet by Charles II. soon after the Restoration as a reward for services and loyalty during the Civil Wars. From this Sir William Cayley the subject of this memoir was but fourth in descent, a rare example of five generations extending over a period of 300 years and one which is mainly accounted for by the late periods in life at which his progenitors entered the bonds of matrimony. Henry Cayley was one of a large family; of his six brothers, the third, Sir Richard Cayley, is an ex-Chief Justice of Ceylon, while the fifth, Dr. William Cayley, is well known as the accomplished physician who has been so many years connected with the Middlesex Hospital.

Henry Cayley was born on Dec. 20th, 1834, and was the fourth son of the late Edward Cayley, J P., and Frances, a daughter of the Rev. Richard Twopeny, M A., rector of Little Casterton in Rutlandshire. At an early age he entered the medical school of King's College Hospital where he proved to be a painstaking and methodical student. At the end of his curriculum, towards the close of the year 1855, when just 21 years of age, he was enrolled as a Member of the Royal College of Surgeons of England. He entered the Bengal army as an assistant surgeon shortly before the Indian Mutiny, served through it, and received the medal when the hostilities were brought to a successful termination. His bent was, however, rather towards the civil than the military side of the great service of which he was a member and, an opportunity occurring, use was made of his special knowledge of diseases of the eye to appoint him to the chair of ophthalmic surgery in the Calcutta Medical College. This appointment he held for many years; the position brought him a large and ever-increasing special practice and great practical knowledge. His skill in the extraction of cataracts and in other operations connected with the eye is still remembered in Calcutta, where his influence in the medical school was great. He was duly elected to a Fellowship of the University of Calcutta. He became a Fellow of the Royal College of Surgeons of England in 1886 and, a year later, on April 29th, 1887, he retired from the Bengal army with the rank of deputy surgeon-general and after a service which extended over a period of more than 30 years. Soon after his return to this country he settled down at Elm Grove, Watford. It was at about this time that he was appointed a member of the Medical Board at the India Office, of which Sir Joseph Fayrer was then the President, but before he finished the usual term of membership, owing to the unexpected death of Dr. D. B. Smith (1889) a vacancy occurred in the Army Medical School at Netley. The professorship of military and tropical medicine was rendered vacant; it was offered to Cayley and was accepted by him. At Netley Cayley had a difficult position to fill: his lectures were rather severely criticised. He practically succeeded to the chair of Surgeon-General Maclean (for Dr. Smith's tenure of the post had been but a short one), whose flow of language and wonderful descriptive power had brought the diseases of the tropics vividly before the young officers in a way that will never be forgotten and is a treasured memory to many. Cayley, although a teacher of considerable experience in India, was not gifted with a good delivery or with any pleasing flow of language, and these circumstances, taken with his rather diminutive stature, quiet, almost shy, manner, and rather low intonation, caused at first a want of appreciation. It was, however, soon found that his lectures were prepared in a most careful and conscientious manner. In respect to his previous opportunities as a teacher it was no fault of his that he was placed in a difficult position at Netley, but it was the fault of a system which could convert, by a touch of the pen, an ex-professor of ophthalmology into a professor of medicine. It is certain that he strove to make himself the master of all modern methods of diagnosis and he followed Dr. Smith's example of spending a considerable period each day in the wards of the hospital and aiding the young officers in the diagnosis and treatment of their cases. In him his colleagues found a loyal supporter on all questions which concerned the well-being of the school and as a member of the senate he did all he could to strengthen the position of the executive. His quiet, sympathetic manner with the suffering, his straightforwardness, his true kindness of heart, and his consideration for others will ever form a bright example and will be remembered by those who were at any time his colleagues.

After holding the professorship for about seven years and on reaching the age limit Cayley finally retired and it was thought that his connexion with the army was closed. He settled at Cherrahurst, Weybridge, where he continued his active outdoor life. When he retired from India in 1887 he brought back to this country a settled habit of early rising which we believe he never relaxed. While at Netley it was a common thing to meet him in the neighbourhood taking a canter soon after dawn or to find him returning after an early swim. He was a warm advocate of yachting both as a source of pleasure and as a means of restoring health and we doubt if any other member of the Royal Southern Yacht Club derived greater satisfaction from this pursuit than did Henry Cayley, although his boat was only a tiny craft. His retirement from Netley, however, was not destined to mean the last of his public services. The South African war was being waged, there rang through England a note which told of the need of more hospitals and officers to administer them; he heard the call of duty and responded, though he had nearly completed his sixty-fifth year. He offered his services to the War Office and was chosen to proceed to the front as the senior officer of the Scottish National Red Cross Hospital, with the rank and title of colonel. In South Africa he did most excellent service, never sparing himself, while his tact and kindly manner helped to make the paths easy for those who had actually to minister to the sick and wounded. He was mentioned in despatches and at the end of the war he returned to this country in the best of health and spirits. He received as his outward reward the South African and the Queen's medals and the decoration of the third class of the Order of St. Michael and St. George. But there was another and a higher reward which came to him and which, though unspoken, was accorded to him by his friends; it arose from the fact that when advanced in years, in a time of trouble, he had given up luxury and ease to undergo certain hardship and great danger More recently he was gazetted "Honorary Surgeon to the King." On his return he again settled at Weybridge where he purchased the home in which he passed his last days.

He married on July 10th, 1862, Letitia Mary, daughter of the Rev. Nicholas Walters, and by her had a family of six sons and two daughters. Three of his sons are serving His Majesty—two in the army and one in the navy. The second son, Dr. Cyril Henry Cayley, is now divisional health officer of the city of Bombay. Of his two daughters, the elder is married to Mr. Charles MacLeod, a Calcutta merchant, and the younger to Lieutenant-Colonel H. R. Whitehead, F.R C S Eng., R.A M.C, who is now in medical charge of the Herbert Hospital at Woolwich. To his widow and to his family we tender our sincere sympathy. We knew something of the man and what he was in his home. To the younger generation he was not only the father but also the companion and friend.

GEORGE RIGDEN, M.R.C.S. ENG., L.S.A.

MR. George Rigden, who died at his residence in St. George's-place, Canterbury, on March 21st, was one of the oldest inhabitants of the cathedral city and a veritable link with the past. His last illness was of only a few days' duration, although his health had been failing for a considerable time and he had been confined to the house for several months. Mr. Rigden was born at Wingham, in Kent, on Dec. 30th, 1815, so that at his death he was in his eighty ninth year. His school education was received at Sandwich and Ramsgate and his medical training was obtained at University College, London, where he obtained a silver medal. In 1837 he became qualified as L.S.A. and was admitted a Member of the Royal College of Surgeons of England in 1844. In 1837 he did temporary duty at the Canterbury Dispensary, to which he was shortly afterwards appointed surgeon and secretary, capacities in which he acted until 1900. He took much interest in questions relating to public health and was one of the pioneer contributors to the literature of the subject, his personal observations being published in his "Report on the Sanitary Condition of Canterbury" and "Vital Statistics of Canterbury." As a practitioner Mr. Rigden was perhaps best known as an accoucheur; he was at an early period of his career convinced of the utility of anæsthetics in midwifery cases; he was also a strong advocate of the forceps and even applied them on one occasion when he was over 80 years of age. In 1881 he published in the Transactions of the Obstetrical Society a "Statistical Report of 5682 consecutive Cases of Midwifery occurring in Private Practice." During 1891-92 he was president of the South-Eastern branch of the British Medical Association As a memorial of his having practised in Canterbury for 50 years he presented to the city a drinking fountain which stands at the corner of Station-road, St Dunstan's. Mr. Rigden married in 1842 and had a numerous family. His wife survives him and their "diamond wedding" was celebrated two years ago; their four sons are all in the medical profession. The funeral took place on March 24th and was attended by a large number of persons, including practically all the medical men of the city.

Medical News.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in the Faculty of Medicine in March the following candidates were successful:—

FINAL EXAMINATION.

Part I.—Francisco da Cunha and H. S Dixon, Owens; John Dixon, R. G. Dixon, and Harold Fearnley, Yorkshire; R. L. Ferguson, Owens; Alfred Gough and H. S. Hayling, Yorkshire; Robert Haslam, Owens; W. B. Hill, J. J. Hummel, and A. J. Landman, Yorkshire; G C. Mort, Owens; C N. Smith, Yorkshire; Harold Spurway, and Douglas Wardleworth, Owens; and Frederick Whalley and F. W. B. Young, Yorkshire

Part II.—P. W. Ashmore, Yorkshire, John Battersby and J. W. Hartley, Owens; F. W. Hayes and S. L. Heald, Yorkshire; W. G. Kinton, W. Y. Martin, Stuart Murray, and S. H. Ryan, Owens; and Bertram Suggitt, Yorkshire.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS —The following candidates have passed the preliminary examination:—

P. N. Allman, J. J. Blake, F. Cassidy, D. F. Curran, H. P. Henay, A. Humphreys, W. S. Johnston, A. R. Mallet, J. Moynihan, J. T. O'Boyle, M C. O'Hara, F E Preston, B. Reilly, S Robinson, Israel Scher, G. C. Sneyd, R. H. F. Taaffe, M. Tobin, B. Wallace, J. F. Williamson, and R. A. Wright.

DONATIONS AND BEQUESTS.—The Prince of Wales has sent a donation of £50 to the Dorset County Hospital.

A vaccination grant has been awarded by the Local Government Board to Mr. S. H. Rentzsch, Week St. Mary, for the third time in succession.

DEATH OF A CENTENARIAN.—Mrs. M. Bishop, who died at Crediton recently, was 103 years old.

THE DEVONSHIRE HOSPITAL.—The report of the committee of management of the Devonshire Hospital and Buxton Bath Charity for the year 1903 states that 2916 in-patients have been admitted during the year, being 247 less than in the previous year. The number of out patients admitted was 209 The average number of patients daily in the hospital was 192·5. The average cost per week of each in-patient has been 15*s.* 9¾*d.* In connexion with this charity there is a Samaritan fund for the purpose of helping needy patients to return to their homes. The hospital, which commenced its beneficent work in the year 1859, has, since its inception, cured or relieved nearly 76,000 patients and the constantly widening sphere of its usefulness entails a heavy expenditure.

A MEDICAL CRICKETER.—Mr. E. M. Grace, M.R.C.S. Eng., L.R.C.P. Edin., the secretary of the Gloucestershire County Cricket Club, is in his sixty-third year. He has made 72 217 runs and taken 10,815 wickets during his cricket career and will doubtless increase these totals considerably during the coming season.

THE LATE MR. J. P. RICHARDS.—Mr. Joseph Peeke Richards, who died at his residence, 6 Freeland-road, Ealing, on March 22nd, in his sixty-fourth year, was a native of Plymouth. He received his medical education at King's College, London, and became qualified as M.R C S. Eng. and L S.A. in 1863 He entered on lunacy practice as assistant medical officer at the Devon County Lunatic Asylum and was subsequently appointed medical superintendent of the female department of the London County Asylum at Hanwell.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates having passed the necessary examination have been admitted Fellows of the College: Mr. J. H. Barrs, L.S A. Lond. (Burton-on-Trent), and Mr. W. F. Law, M.B., B Ch Dub. (British Guiana).—At a meeting of the President, vice-president, and council, held on March 24th the following motion was passed unanimously:—

[illegible]

ST. BARTHOLOMEW'S HOSPITAL.—The following donations have been received by the treasurer of St. Bartholomew's Hospital towards the building fund:—The Union of London and Smiths Bank (Limited), £210; Stafford Northcote and Co. (Limited), £26 5*s.*; Dr Clement Godson, £52 10*s.*; National Provincial Bank of England (Limited), £105; London and Westminster Bank (Limited), £210; the Capital and Counties Bank (Limited), £105; Mr. R. C. Ackland, £25; and London and County Banking Company (Limited), £65. Mr. John Tann of 11, Newgate street, E C., has given a steel chest and three wrought steel collecting boxes to be placed at the entrances to the hospital.

VISITING PHYSICIANS AT POOR-LAW INSTITUTIONS.—At a recent meeting of the Bristol board of guardians a suggestion was made by several of the members that the gratuitous services of visiting physicians might be obtained. The general purposes committee, however, reported at the meeting of the guardians held on March 25th to the effect that such an arrangement could not be made without remuneration being provided and it recommended that the subject should be deferred for the present. The report was adopted, one of the guardians remarking that physicians were ready to give their services to any charitable institution but a Poor law establishment was not a charitable institution in the sense that a hospital was.

UNIVERSITY OF OXFORD.—NOTICE OF THE EXAMINATION IN PREVENTIVE MEDICINE AND PUBLIC HEALTH, MICHAELMAS TERM, 1904 (D P H. EXAMINATION).—The examination for the diploma in Public Health will commence on Tuesday, Nov 22nd, at 10 A.M, in the schools. The examination is in two parts, conducted partly in writing, partly *vivâ voce*, and in each subject partly practical. The first part comprises the application of chemistry and physics to general hygiene. The second part comprises the following subjects: general pathology, with special relation to infectious diseases; the laws relating to public health; sanitary engineering; and vital statistics. Both parts may be taken together at the same examination or they may be taken at separate examinations, but no one is deemed to have satisfied the examiners in Part 2 unless he has satisfied the examiners in the subjects of Part 1. The fee for admission to each part is £5 A diploma is issued to every candidate who has passed in both parts of the examination but no diploma or certificate is given in any other circumstances. Candidates (who are not necessarily members of the University) must have their names on the Medical Register and must have satisfied all the rules of the General Medical Council of the United

Kingdom relating to the admission of candidates for diplomas in Public Health which are in force at the time. Candidates must send in their names by letter to the secretary to the Boards of Faculties at his office in the Clarendon-buildings, Broad-street, Oxford, not later than 10.30 A.M. on Tuesday, Nov. 8th, at the same time inclosing the statutable fee and full evidence of having satisfied the above requirements.

BRISTOL ROYAL INFIRMARY.—The annual meeting of the governors of the Bristol Royal Infirmary was held on March 22nd, under the presidency of Sir Charles Cave. The medical report stated that the in-patients numbered 3293, compared with 3281 in 1902. There were 44,263 out-patients treated, as against 41,761 in the previous year. The financial statement showed that the total ordinary income of the institution was £11,041 and the total ordinary expenditure was £16,451. The total adverse balance of the infirmary is now nearly £16,000. A new casualty department and lift, costing about £4000, are urgently needed; the committee therefore proposes to ask the public for a sum of not less than £20,000 and confidently expects that the citizens of Bristol will readily respond.

ROYAL LONDON OPHTHALMIC HOSPITAL.—Owing to the death of H.R.H. the Duke of Cambridge, patron of the Royal London Ophthalmic Hospital (Moorfields) and president at the last dinner held in aid of the funds of the institution, the centenary festival dinner in aid of the funds of the hospital, arranged for Friday, April 22nd, has been postponed to Tuesday, May 10th. The dinner will take place in the Grand Hall of the Hotel Cecil and Sir Charles Wyndham has kindly consented to preside on this occasion and to enable him to do so he is generously closing his theatre on that night. The arrangements for the dinner are in the hands of the Social Bureau, 30, New Bond-street, London, W., where all information may be obtained.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on March 24th the following gentlemen, having passed the necessary examinations, were admitted Fellows of the College:—John Evans Hadden Bennett, M.B., C.M., County Cork; Arthur William Stark Christie, M.B., Ch.B. Edin., Edinburgh; Owen Gilmore, L.R C.S. Edin., Edinburgh; Harold Edgar Atheling Jackson, M.R.C.S. Eng., L.R C.P. Lond., Victoria, Australia; Alfred Dudley Eskell Kennard, M.R.C.S. Eng., L.R C.P. Lond., Hampton Wick, Middlesex; William Lloyd, L R.C.S. Edin., London; Maitland Bodley Scott, M.R C.S. Eng., L.R.C.P. Lond., Bournemouth; Harry Moss Traquair, M.D., C.M. Edin., Edinburgh; and Daniel John Cunningham, D.C.L., LL D., M.D., D.Sc., professor of anatomy in the University of Edinburgh, was also elected a Fellow of the College without examination. The medal and set of books forming the Bathgate memorial prize, presented to the College by Colonel William Lorimer Bathgate in memory of his late father William McPhune Bathgate, Fellow of the College, was awarded to Miss Helen Meldrum McMillan for the highest marks obtained in competitive examination in materia medica and therapeutics.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 23RD.

Atmosphere of the Underground Railway.

Mr. WEIR asked the President of the Board of Trade whether, having regard to the fact that the atmosphere in the Metropolitan Extension Railway between 8 P.M. and midnight was specially foul through being surcharged with smoke emanating from coal of a highly bituminous character, he would represent to the company the desirability of using coal of a smokeless nature.—Mr. GERALD BALFOUR replied: I have communicated with the railway company on the subject and in reply they inform me that on the extension line from Baker-street, as well as on the Inner Circle railway, the best hard Welsh smokeless coal is always used and that inspectors are employed to see that the engine-drivers fire in a proper manner. It is added that the railway from Baker-street through the tunnel is to be worked by electricity at an early date.

The Plague at Johannesburg.

Sir WALTER FOSTER asked the Secretary of State for the Colonies whether he had any official report as to an outbreak of plague in the coolie location at Johannesburg, and if so whether he would state the number of cases and the number of deaths up to March 19th among the coolies, Kaffirs, and whites.—Mr. LYTTELTON replied: The latest telegrams from Lord Milner on this subject are as follows. March 20th. No. 1. Bubonic plague has broken out in the coolie location here. It is a virulent outbreak, 30 deaths having occurred out of 38 cases within a few days. Though the nature of the disease was only recognised yesterday steps have been already taken to remove all patients to a special camp to the north of the town. Owing to the fact that the possibility of outbreak has been foreseen for some time the site of the camp was already chosen and necessary arrangements made, while tents are ready and will be erected immediately. There will be thus no difficulty about isolation and proper treatment of all suspect cases. Outbreak confined to coolie location which forms part of insanitary area recently expropriated by municipality. Town council is thus in position to clear the location at once, to transfer the coolies to a new site outside the town, and to disinfect the whole space. It has all necessary legislative powers and administrative arrangements have as far as possible anticipated the need which has arisen. There is thus every reason to hope spread of disease may be promptly checked. Mining area so far quite unaffected. March 22nd. No. 2. Your telegrams of March 21st, No. 2 and No. 3. Present position of plague is as follows: suspected cases reported, 47 coloured, six white; deaths, 40 coloured, two white. Outbreak appears to be well in hand and I do not think it necessary to engage services of Professor Simpson, especially as I have a first-rate bacteriologist and excellent medical staff on the spot and the public here have complete confidence in them.

THURSDAY, MARCH 24TH.

Further Particulars about Plague.

The second reading of the Consolidated Fund Bill afforded a convenient opportunity for raising a discussion on the circumstances connected with the outbreak of the plague at Johannesburg.—Sir WALTER FOSTER asked for information. Had the disease been brought into the city by the imported Asiatic labourers? It appeared to have broken out in an Indian location and, of course, it was known that Indians were specially liable to the malady. A suspicious circumstance in connexion with the matter was that there had been a heavy rate of mortality among the people working in the mines and this had been said to be due to a form of pneumonia following on after influenza. As the plague itself was pneumonic he was not without his suspicions that the mortality among the mine workers might have been due to a disguised form of the plague which had been present in the locations for some time. At all events, the point was worth looking into in order to prevent any future possibility of the disease in its milder form being overlooked. What was the source from which the plague had been introduced? There were several possibilities. It might have been brought by recruited Indian labour or by foods imported from India or China. Plague was often carried by animals, fowls, pigs, dogs, and cats—which for weeks after their infection presented no suspicious symptoms. Rats, the commoner carriers of plague, were affected much sooner.—Dr. HUTCHINSON urged that each Chinese coolie should be medically examined before entering the compound and that the site of the compound should be chosen by a thoroughly qualified man.—Mr. LYTTELTON, in his reply, said that he personally and the Government were much indebted to the two high authorities on medical matters who had just addressed the House. As to the fear that the introduction of Chinese labour might be attended with danger at present he could give the assurance that a medical officer would examine each coolie in China before he was embarked and that a surgeon-superintendent would accompany each ship with the absolute duty of looking after the health of all the coolies on board. Vaccination would take place and again in South Africa another health examination would be made, so that so far as human precaution could secure it the coolies would be medically fit. The honourable Member (Sir Walter Foster) was aware that the sources of this bubonic plague were still a matter of scientific obscurity. He agreed with what had been said about its transmission by animals. That much, he understood, had been ascertained, but if they were to compare, for instance, the sources of malaria with the sources of bubonic plague they would find that whereas science had made great advances in the ascertainment of the sources of malaria it had not reached nearly so satisfactory a point with regard to the sources of bubonic plague. The suggestion that every precaution should be taken for knowing beforehand the precise spot they would choose for isolation in case of an outbreak of bubonic plague was a most eminently reasonable one and he could hardly believe that the medical advisers in the Transvaal would not readily fall in with it. In fact, he thought it would be admitted that the circumstances with regard to the present outbreak showed not merely that every foresight and vigilance were exercised but the actual measures had been taken and a site actually chosen to guard against the possibility of an outbreak.—Sir WALTER FOSTER interrupted to ask why an outbreak had been anticipated.—Mr. LYTTELTON said he could not bind himself to accuracy on that point. He had no exact information but he believed that what had happened was this. It had been for some time a complaint in Johannesburg that the drainage system was deplorably bad, that insanitary areas existed, and one of the deplorable features of the shortage of labour was that the Johannesburg municipality had actually been unable to carry out the sanitary reforms which they had promoted. There was, therefore, a condemned area in Johannesburg. It was inhabited, not necessarily by Indian coolies, but by Indian traders and other Indian inhabitants. These were not recent importations; a good many Indians were resident in Johannesburg in President Kruger's time. Evidently one of the areas which they inhabited became insanitary and was condemned, but the measures which would have been taken to clear out the area had only labour existed became impossible. No doubt Lord Milner and the authorities of the [illegible] unicipality, seeing that these areas had been [illegible] foresaw that some epidemic might occur, [illegible]y deplorable that the areas could not have been cleared it probably would have been more deplorable to have turned the Asiatics out into the streets in the cold nights. Let him say this—that with regard to the introduction of Chinese any man would be mad to introduce Chinese into a place where plague existed or at any rate where plague was not most scrupulously isolated and where he had not obtained medical advice of the highest eminence that it was safe to introduce such labour. He thought, without taking upon himself any of the functions of the medical profession, he might say that no such introduction would be contemplated for a moment by the authorities of the Transvaal unless they were advised on medical advice that such a proceeding was unattended with risk.

Vaccination Exemptions.

Mr. WEIR asked the President of the Local Government Board how many certificates of exemption from vaccination were granted during the year ended Dec. 31st, 1903.—Mr. LONG replied: The returns made to me show the number of certificates of conscientious objections received by the vaccination officers during each year, and this number may be taken as substantially agreeing with the number granted during the year. The returns for 1903 are not quite complete, but the number of certificates of the kind referred to received during the year may be stated approximately as 37,200.

Dentistry in East Africa.

nticipate special
difficulties at Johannesburg and in these circumstances I can give no undertaking to prevent the entry of Chinese labourers as soon as the Transvaal Government is advised that such introduction can take place without undue risk.

Vaccination of Pauper Children.

Mr. WEIR asked the Secretary for Scotland whether the circular letter recently issued by the Local Government Board for Scotland enjoined the compulsory vaccination of all pauper children who did not exhibit satisfactory marks of primary vaccination; whether medical officers of poorhouses were required to examine the vaccination marks of all pauper inmates of poorhouses and to revaccinate when that course seemed desirable, and whether medical officers would be instructed to keep a record of the number of inmates examined and the number revaccinated.—Mr. GRAHAM MURRAY replied: I am informed that the object of the circular was to secure that all the inmates of poor-houses should be vaccinated but the circular does not enjoin the compulsory vaccination of the class of children referred to, it recom-
es should
of their
lsory re-
cted the
medical officers of poorhouses to keep a record of the number of inmates examined and the number revaccinated and they prefer in the meantime to leave this to the discretion of poorhouse committees.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ANDERSON, T. L., M.B. Melb., has been appointed a Member of the Honorary Medical Staff of the Fremantle Public Hospital, West Australia.

ASTLES, HARVEY EUSTACE, M.D. St. And., has been appointed President of the Dental Board, West Australia.

BARTON, CHARLES M., L.R.C.P. Lond., M.R.C.S., has been appointed Anæsthetist to the Gordon Hospital, Vauxhall Bridge-road, S.W.

BLACKBURNE, G. H. S., M.B., Ch.B. Melb., has been appointed *pro tem.* Acting President of the Central Board of Health, West Australia.

COLCLOUGH, W. FRANK, M.D., B.C. Cantab., has been appointed Medical Officer to Out-patients, Yeatman Hospital, Sherborne.

COOK, A. H., M.B. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Medical Officer to the Infants' Hospital, Hampstead, N.W.

COX, ALLASTER EDWARD, M.B. Edin., J.P., has been appointed Member of the Licensing Court for the Licensing District of Forbes, Ne[illegible]

HOPE, J. [illegible] been appointed *pro tem.* Acting [illegible] at the Fremantle Lunatic Asylum, [illegible]

FULLERTON, ALEXANDER YOUNG, L.R.C.P. Lond., M.R.C.S., has been appointed Deputy Licensing Magistrate of the Licensing Court for the Licensing District of Murrurundi, New South Wales, Australia.

KELYNACK, T. N., M.D. Vict., M.R.C.P. Lond., has been appointed Honorary Physician to the Infants' Hospital, Hampstead, N.W.

LAIDLAW, J. H., M.D., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

LINTON, EDWARD, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed [illegible]ment Medical Officer and Vaccinator at Welling-[illegible] Wales, Australia.

LONGHURST, FREDERIC W., L.R.C.P. Lond., M.R.C.S., has be appointed Anæsthetist to the Gordon Hospital, Vauxhall Brid road, S.W.

MACLAURIN, CHARLES, M.B., M.S. Edin., has been appointed Member of the Police Medical Board, New South Wales, Australi

MONCKTON, WILLIAM, L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Medical Officer of Health of Portishead (Somerset).

MORITZ, S., M.R.C.P. Lond., has been appointed Lecturer on Disea of the Throat and Nose at the Victoria University of Mancheste

PAGE, HERBERT MARKANT, M.D. Brux., M.R.C.S., L.S.A., D.P. Cantab., has been appointed Medical Officer of Health of Yeovil.

STUART, HACKWORTH, M.D. Lond., D.P.H. Cantab., M.R.C.S., L.R.C. Lond., has been appointed Medical Adviser to the Hanley Edu tion Committee.

Vacancies.

For further information regarding each vacancy reference should made to the advertisement (see Index).

BEDFORD COUNTY HOSPITAL.—House Surgeon. Salary £100 p annum, with apartments, board, and laundress. Also Hou Physician. Salary £60 per annum, with apartments, board, a laundress.

CHESTER COUNTY ASYLUM.—Third Assistant Medical Officer, unmarri Salary £160 per annum, with board, lodging, and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOME Shadwell, E.—Assistant Physican.

EAST SUFFOLK AND IPSWICH HOSPITAL.—Second House Surge unmarried. Salary £80 per annum, with board, lodging, a washing.

GREAT YARMOUTH HOSPITAL.—House Surgeon. Salary £90 p annum, with board, lodging, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton Resident House Physicians for six months. Honorarium of £25.

HULL, VICTORIA HOSPITAL FOR SICK CHILDREN.—Lady House Su geon. Salary £50 per annum, with board and laundry. Al Lady Assistant House Surgeon. Salary £40 per annum, wi board and laundry.

LIVERPOOL STANLEY HOSPITAL.—Senior House Surgeon. Salary £1 per annum, with board, residence, and washing.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—House Surgeon, u married. Salary £120, with board and residence.

MANCHESTER ROYAL INFIRMARY CONVALESCENT HOSPITAL, Cheadle. Resident Medical Officer, unmarried. Salary £150 per annu with board and residence.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medic Officer. Salary £70 per annum, with board, residence, a washing.

PRESTON ROYAL INFIRMARY.—Assistant House Surgeon. Salary £ per annum, with board, washing, &c.

READING, ROYAL BERKSHIRE HOSPITAL.—Assistant Physician.

ST. MARY'S HOSPITAL FOR SICK CHILDREN, Plaistow, E.—Assista Resident Medical Officer, unmarried, for six months. Salary at ra of £80 per annum, with board, residence, and laundry.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-ro[illegible].—Honora Surgeon.

SOCIETY OF APOTHECARIES OF LONDON.—Examiner in [illegible] Surgery.

STAFFORD GENERAL INFIRMARY.—Assistant House [illegible] Surgeon for s months. Honorarium of £40, with board, reside[illegible] &c.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND [illegible] the Women, Waterlo road, S.E.—Resident Medical Officer.

WEST LONDON HOSPITAL, Hammersmith-road, [illegible] W.—House Surgeo Board, lodging, and laundry.

Births, Marriag[illegible], and Deaths.

BIR[illegible]

BEEGLING.—On March 22nd, at [illegible], the wife of D. N Beegling, B.A., M.B., C.M., of a [illegible]

BENSON.—On March 19th, at The [illegible] Claydon, Bucks, th wife of P. L. Benson, M.A., M.D. [illegible]

HUNTER WOODS.—On March 21st, at [illegible], New Milton, S. Hants the wife of H. Hunter Woods, M.R.[illegible] D.P.H., of a daughter.

LANDER.—On March 22nd, at Hather[illegible] Derbyshire, the wife o H. W. G. Lander, M.B., of a son.

ROBERTS.—On March 23rd, at South Eato[illegible], S.W., the wife o Edward A. Roberts, M.D., of a daughter.

MARRIAGES.

CRAWSHAW—RADFORD.—On March 24th, at New College Chapel, Upper Avenue-road, N.W., Ernest John Crawshaw, M.R.C.S. Eng., L.R.C.P. Lond., to Cicely Kate, third daughter of George Radford, M.A.

WOOD—BROOKER.—On March 26th, at St. George's Church, Bloomsbury, Thomas Jason Wood, M.D., to Edith Isabel, second daughter of the late J. W. Brooker.

DEATH.

RICHARDS.—On March 22nd, at Freeland-road, Ealing, W. Joseph Peeke Richards, M.R.C.S., L.S.A., aged 63 years, late Medical Superintendent at the London County Asylum, Hanwell.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A BOGUS AMERICAN UNIVERSITY.

A PERSON named Mather, styling himself "Financial Secretary and General Agent for the American College of Law and Washington University," has written to members of the English medical profession and doubtless to other professional gentlemen in the following terms:—

> AMERICAN COLLEGE OF LAW AND WASHINGTON UNIVERSITY, Washington, D.C. Chartered under Act of Congress. William M. Farr, L.L D., President. E. Mather, A.M., M.D., L L.D., Financial Secretary and General Agent. P. O. Box 223, Detroit, Mich.
>
> *Corporate Departments.*—The American College, the American Law School, American Business College, American Shorthand College, American Normal College, American College of Music, American College of Oratory, American College of Diplomacy, [illegible] *American College of Government, American Correspondence Colleges.*
>
> *Detroit, Mich., March 11th, 1904.*
>
> MY DEAR SIR,—Having your name before me, and knowing your Professional standing, I am desirous of drawing your attention to the following Colleges, and, if I can be of service, in any way, it will please me to have a communication, as our departments are in Science, Art, Law, and Medicine, etc., I am sure I can interest any such persons in various ways.
>
> We have a first-class University in all respects, as you will see and, one which the student may be justly proud of, located at the National Capitol, Washington, D.C., this should be sufficient guarantee regarding its standing among our best Institutions of Learning in this Country. Washington is a very pleasant and beautiful City, with all the surroundings for health and comfort that a student can desire, and, where over half a million people visit annually.
>
> A Journal is published by the law department and is mailed to subscribers at a *nominal cost of one dollar per year throughout the* United States and one dollar and fifty cents in Foreign Countries.
>
> I enclose a slip, which will explain for itself to men of distinction, and at the same time soliciting correspondence from students: and those desirous of the standing and an explanation of both Institutions of Learning, would do well to remit one year's subscription.
>
> An early reply from you, will be greatly appreciated. I am,
>
> Very respectfully yours,
>
> E. MATHER.

We need hardly say that Mather is practically a writer of begging letters and that the institution with the long-winded title in whose behalf he acts is the usual bogus university. The slip which Mather encloses runs as follows:—

> If you are desirous of any honorary degree, I may be of service to you, as our law department issues to men of distinction the *Degrees of L.L B., L LM., D.C.L., and L.L D.*, but these men must fill in a record of data signifying their standing and giving any works or write-ups in which they have a distinction. I will be happy to hear from you, and will send, if required, the necessary documents to be filled in as this College is up to date and legally chartered as you will see by the enclosed letter-head. If you are interested and desire to see the announcement, send one dollar for subscription for one years legal Journal. Foreign Subscriptions, one dollar and fifty cents.

We cannot think that any medical man would be so absolutely short-sighted as to put any trust in Mather's representations. He is simply *hunting for 1 dollar and* 50 cents as a foreign "subscription for one year's *Legal Journal*" with the hope of being able to extract a larger sum from persons weak enough to desire to obtain the letters of an honorary doctorate to their name. The flam is so obvious that we should not waste space upon cautioning our readers in the matter were it not that we have heard of persons *who have replied to* Mather as if he were a serious and honourable person (neither of these persons was a medical man). We do not, by the way, think much of the ingenuity of Mather's designs upon the British purse. What does it matter to a person in England if the "first-class university" is "located at the National Capitol, Washington, D C. ...... a very pleasant and beautiful *city*"? And how does the financial secretary and general agent of a first-class university in Washington come to discharge his duties from "P O. Box 223, Detroit, Mich."? Mather would seem to possess the impulses of roguery but to be scantily endowed with the astuteness that makes for success.

CHEAP CREDIT *v.* USURY: A NATIONAL SCHEME.

WE have received from Mr. Thomas Farrow of 67, Gracechurch street, E.C., who is the author of "The Money-lender Unmasked," a letter in which he informs us that in connexion with his proposed National Credit Institution for the suppression of 60 per cent. money-lending and its attendant evils he has, in conjunction with the best known men of the day, registered a people's bank under the Industrial and Provident Societies Act and has received the necessary certificate from the chief registrar of friendly societies. The bank has been empowered to open a central establishment in London and to found branches throughout the kingdom. The share capital, says Mr. Farrow, has been arranged so that even a working man can become a shareholder by the investment of £1, payable by instalments, and so as to prevent the bank from falling into the hands of large capitalists the holding of any individual shareholder cannot exceed £200 5 per cent. dividend is guaranteed on shares and 3½ per cent. on deposits. The institution will *be managed by men specially qualified for the purpose* and no ornamental person will find a place on the board. The success of the scheme largely depends upon the prompt co-operation of the public which is invited. We cannot commen particularly upon the scheme until we learn more details but we can well imagine the difficulties of such a business, as there are some people "clever" enough even to defraud keen money-lenders, and if a low rate of interest is charged it will not allow for many serious losses. We have no doubt that Mr. Farrow will take care that the individual shareholder whose holding may not exceed £200 is not the nominee of a large capitalist whom the bank desires to keep outside. There is no question whatever that institutions are wanted from which a struggling and respectable tradesman or professional man may in an emergency obtain a small loan of £20 to £50 without falling into the hands of a vampire, and if Mr. Farrow can provide such institutions upon practical lines we wish him success.

A STORY OF ELECTRICITY.

A CORRESPONDENT writing in the *Scientific American* of March 19th describes some phenomena unusual in the United Kingdom. He says:—

> *I have been called on to investigate a peculiar case which* has puzzled me and I would ask your advice on the same. The case in question is a house which seems to be a veritable frictional machine. By walking on the carpet a spark can be produced by bringing the finger near any metal substance, whether grounded or not, such as a brass tack in furniture, picture frames, &c. If this condition existed to a small extent nothing would be said, but it is to such an extent as to be very objectionable. The house is heated by a hot-air furnace and everything about the house is very dry. I have suggested keeping water pan in furnace constantly filled with water, as I believe that the moisture produced will tend to allow the charge to neutralise itself. Two persons coming in contact with each other produce a spark. Can you suggest a remedy for this?

THE PRICE OF A HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Would any of your readers be kind enough to give the approximate cost per bed of a thoroughly up-to-date hospital of 50 beds, including out-patient department and offices, the site being given?

I am, Sirs, yours faithfully,

March 24th, 1904. M.B., B.C.

A CRYPTIC ASPECT OF THE CRY OF PAIN.

To the Editors of THE LANCET.

SIRS,—Would you kindly allow me to ask through the medium of *THE LANCET for references* to any reports or observations in any European language on a rather cryptic aspect of the cry of pain? Not the aspect which is made so much of in current literature, of a relief from a nervous strain, or the aspect of a communication to others—i.e., as a cry of distress, a cry for help; I mean its purely afferent aspect, the value, namely, that the cry of pain possesses in consequence of reaching the ear of the sufferer who utters it. Thanking you in anticipation,

I am, Sirs, yours faithfully,

March 24th, 1904. PSYCHOLOGUS.

THE BRITISH WEATHER CHART FOR 1904.

WE have received *from the publishers, Messrs. R. Morgan and Co.*, 65, Westow-street, Norwood, S E., a copy of the British Weather Chart for 1904, which has been compiled by Mr. B. P. Jenkins, F.R.A.S. The chart sets out the thermometrical and barometrical forecasts for the whole year and under the heading of each month prognosticates the general condition of the weather, the prevailing winds and temperature, and the average rain, while dates are given round which it is suggested particular falls in the temperature or falls of rain may be expected to appear. Of course, no prophet can expect to be praised till after his prophecies have been found true, so that we only commend Mr. Jenkins's work to our readers in a modified manner, but we may say, firstly, that his *tracings are perfectly* easy to comprehend, secondly that his prophecies have been accurate more or less for the first quarter of the year, and thirdly that there is nothing Delphic about his utterances—he does not "hedge" or [illegible] terms. He definitely states for example that the [illegible] l that the [illegible] average, [illegible] and 20th. If the next few weeks prove Mr. Jenkins to have been right in his vaticinations we shall regard the chart with considerable reverence for the rest of the year. The price of the chart is 6½d.

THE MEDICAL OFFICER OF NO. 2 DISTRICT OF BARNSLEY UNION.

SOME difficulty has apparently arisen in connexion with the appointment of a medical officer for the No. 2 district of the Barnsley union. The circumstances are these. In March, 1903, Dr. Andrew Thomson and Dr. Arthur E. White were candidates for the post and the latter was appointed for one year only. This limitation in time of the appointment, which is contrary to precedent but which was acquiesced in by the Local Government Board, was apparently made in order that Mr. O. F. Rowley, the former holder of the post, might continue to hold the office of public vaccinator for another year and so obtain the vaccination grant. At the beginning of March, 1904, the appointment was advertised and Dr. Thomson was appointed. The Local Government Board, however, has not yet ratified the appointment. It seems to us that the guardians have acted somewhat hardly in ignoring Dr. White's claim for reappointment. He has done the work of the post for a year and no complaints seem to have been made as to the manner in which he carried out his work. The guardians are, of course, within their legal right in appointing Dr. Thomson, but we think that Dr. White had certainly a moral claim to the post. From a copy of Dr. Thomson's application and testimonials which lies before us we see that he submitted four testimonials from non-medical men.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—In reply to an inquiry in THE LANCET of March 26th, p. 906, as to a home for a semi-imbecile boy aged seven years, allow me to say that the Royal Albert Asylum, Lancaster, now described as a "training school for the feeble-minded of the northern counties," receives cases of the poorer class at 25 guineas per annum without election. Applications should be made to the principal and secretary, Mr. J. Diggens. I am, Sirs, yours faithfully,

March 26th, 1904. G. E. S.

"N" RAYS AND THE NERNST LAMP.

THE Nernst electric lamp has been twice mentioned in THE LANCET recently, in an annotation which appeared in our columns on March 26th, p. 889, dealing with the "n" rays and the more newly discovered "n_1" rays and in a letter from Mr. A. A. Campbell Swinton published in THE LANCET of March 5th, p. 685. These rays have been discovered by M. Blondlot to be emitted by the Nernst electric lamp and a short description of this lamp may therefore be of interest to our readers. The principle of the lamp was invented by Professor Walther Nernst of the University of Gottingen in 1898, but since that time many experiments have been necessary in order to perfect the invention and to make it a really practical lamp for public use. A paper was read on the lamp at a meeting of the Society of Arts held on Feb. 8th, 1899, by Mr. James Swinburne, M.I.C.E., vice-president of the Institution of Electrical Engineers, London, and a full report of the paper, which also included some interesting remarks on the Auer or Welsbach mantle, was published in the journal of the Society of Arts dated Feb. 10th, 1899. These remarks are interesting as M. Blondlot has also found the "n" rays to be given off by these incandescent gas mantles. To make the illuminating filament or rod of the Nernst lamp Professor Nernst took some highly refractory oxides or so called "rare earths" as his material, chiefly zirconia, we believe, and the material was worked up into little white rods of about the size of an ordinary pin. Each rod was mounted on two platinum wires and a little paste made of refractory oxides was applied to the joints. The little rod or filament with its two wires was then mounted in a holder which fitted ordinary electric-light fittings. Highly refractory oxides are notoriously good insulators at normal temperature but such insulators are electrolytes when hot. Therefore in order to make the rods conduct well they have first to be heated to from 600° to 800° C. when they incandesce and yield a beautiful white light of great economy. This heating of the rod is done by means of a "heater" spiral which is either made of kaolin wound with platinum wire or of a particular resistance material made of graphite and clay or some other substances. This open spiral travels around the whole length of the rod but does not touch it. In the "Luna" Nernst lamp (the newest type) the rod is outside the "heater" and thus shadows are obviated. When the switch is turned on the heater spiral becomes red hot and heats the straight rod in the centre up to the temperature at which it conducts well whereupon it emits a brilliant light and the heater spiral is simultaneously cut out of circuit. The lamp is also supplied with a steadying resistance consisting of an iron wire in an exhausted glass tube but this is inclosed with the automatic cut-out apparatus in the upper part of the lamp and is not usually visible. The resistance and burner, which latter has a life of about 600 hours, can be replaced and renewed from time to time without damage to the remaining parts of the lamp. This electric lamp practically will not work in a vacuum and a peculiar feature is that it may be lighted with a match or a spirit lamp—that is, the small illuminating rod may be heated up by such means to overcome its normal resistance and to make it conduct electrically. The watt consumption per candle-power of the Nernst lamp varies from 0·88 to 1·70, while that of the ordinary incandescent vacuum lamp with its carbonised vegetable filament so familiar to all varies from 2·50 to 4 watts per candle-power according to the efficiency at which it works, so that incidentally the saving of current in favour of the Nernst lamp is considerable. The clock tower Houses of Parliament is illuminated by these lamps an Canadian arch was brilliant with them at the time of the Coro festivities, while they have recently been installed in many sho and offices in the United Kingdom, on the continent, and in t United States of America and may conveniently be seen in many the Aerated Bread Company's shops in London where they ha recently been installed. The lamp can be bought in London fr the Electrical Company, Limited, 122, Charing Cross-road, W.C.

THE PIED PIPER OF HAMELIN: A SUGGESTED ORIGI OF THE LEGEND.

To the Editors of THE LANCET.

SIRS,—No adequate explanation of the famous legend of the P Piper has hitherto been offered, so far as I am aware, though attempt has been made to connect it with the child-crusades whi were inaugurated when the word went forth that the Holy Sepulch was recoverable to Christianity by the pure and innocent in hea But this interpretation cannot be maintained, for the child-crusa took place in the twelfth and not in the thirteenth century, to wh latter period the episode of the Pied Piper is very definitely ascrib Yet that it records, under the guise of a fairy tale, some histori event, is certain, for the actual date, June 26th, 1284. is inscribed the wall of an ancient house in the town and the municipal archi are dated from the calamity. Grimm has collected a list of authorit who speak of the event as an historical fact. (Baring Gould: Curio Myths of the Middle Ages. The date given in Browning's poem diffe for some reason.)

The story, of course, is an adaptation of the ancient world-myt current among diverse races, of the magic music compelling all w heard to follow. In its present application it tells of a mediæval m European town infested with rats. A magician appears who entic the rats into the river and then, out of revenge for the parsimony of t citizens, beguiles the children into a chasm which gapes without t gates.

The explanation I would suggest is that this legend records visitation of plague to Hamelin. *Acting on this supposition* we fi the antecedent mortality among the rats which, thanks to the u hygienic habits of the citizens, had hitherto swarmed in the town. may even be that some travelling magician had acquired the art inoculating the rats with a disease which he had not learnt to conne with pestis major. The dead rats are cast into the river Wes and then follows an outbreak of the Black Death, the mortality fro some local cause being greatest among the children and their corps being borne along the Bungen-strasse—

> "Where anyone playing on pipe or tabor
> Was sure for the future to lose his labour,
> Nor suffered they hostelry or tavern
> To shock with mirth a street so solemn"—

to the plague-pit dug in the mountain-side without the city. Th date fixed for the disappearance of the children would perhaps be t occasion of finally filling in the pit after the staying of the pestilenc The thirteenth century was the century of the "Black Death"—wa after wave ravaged Europe. 1284 was not one of the great plague yea but in the intermediate periods there were frequent more or le localised outbreaks. I am, Sirs, yours faithfully,

J. B. MACKINTOSH, M.R.C.S. Eng., L.R.C.P. Lond.

Hampstead, March 22nd, 1904.

LEGAL *v.* MEDICAL ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—A few days ago a respectably dressed man applied to a Lond magistrate for advice with respect to his property. The magistrate once rebuked him and told him to apply to a respectable solicitor w if necessary would instruct a barrister. How low is the standard of t medical profession towards its poorer practitioners. Here you have t leaders of the profession giving their advice gratuitously to thousan well able to pay the poor practitioner. In some of the London ho pitals they have to my mind reached the lowest level—they charge 3 a bottle to last a week, and yet these men propose a Bill to preve their poorer brethren from prescribing and selling a bottle of medici for 6*d.*

It is too disgusting and should make physicians and surgeo of good class withdraw their services from such institutions. To t indigent poor the relief is honourable but to the respectable low middle class at 3*d.* a bottle is a disgrace to any honourable ma unless he is starving, connected with any profession.

I believe there is a step lower in the east-end where a medi carries on a pseudo-charitable religious institution and gives advi and medicine for a penny a week.

I scarcely believe the bulk of medical men in England have a knowledge of these facts nor the free-giving benefactors to the institutions.

I trust you will allow it to be brought to their notice.

I am, Sirs, yours faithfully,

March 28th, 1904. M.R.C.S., L.R.C.P.

◆

Nemo.—(1) The value varies according to the amount of opposition, t length of introduction, the possibility of a transference of appoin ments, &c.; (2) special arrangements to meet the contingency of t *sickness, total incapacity, or death of one of the partners* shoul always be made in the agreement.

T. G. R.—We consider that the circular note in question may be sent.

Medical Diary for the ensuing Week.

OPERATIONS

METROPOLITAN HOSPITALS.

MONDAY (4th)—London (2 P.M.), St. Bartholomew's (1.30 P.M., St. Thomas's (3 30 P.M.), St. George's (2 P.M.), St. Mary's (2 30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9 30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.).

FRIDAY (8th).—THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi terrace, Strand, W.C.).—8 P.M. Council Meeting. Paper:—Dr. J. Howard-Jones: The Control of Measles Epidemics.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Clinical Evening. Cases will be shown by Dr. S. Taylor, Dr. Ball, Dr. Saunders, Mr. Lunn, Mr. Paton, Mr. Pardoe and others.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases, Specimens, &c., will be shown by Dr. StClair Thomson, Mr. P. de Santi, Dr. L. Lack, Mr. H. Tod, Dr. H. Tilley, and others.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8 30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received: *Aberdeen Free Press, Daily Mail Darlington and Stockton Times, Daily News, Daily Chronicle, Hull and Lincolnshire Times, Westminster Gazette, Leeds and Yorkshire Mercury, South Bucks Free Press, Guernsey Star, Hertfordshire Mercury, Standard, South Wales Daily News, Surrey Advertiser, Coventry Herald, Birmingham Daily Mail, Reading Mercury, Mining Journal, Local Government Chronicle, Liverpool Courier, Westminster Gazette, Pall Mall Gazette, Irish Times (Weekly), &c.*

back of the head coming into violent contact with some resisting object, or else from blows applied directly to the various parts of the skull. In these cases there can be no question of compression. The elastic properties of the skull also are much exaggerated and the peculiar formation of the base, with its greatly varying areas of resistance, is not sufficiently taken into account. The skull, also, can in no sense be regarded as a sphere, since the vault forms less than two-thirds of a complete sphere, the base passing inwards from the lower limits of this segment in a more or less horizontal direction. Bilateral compression never results in a fracture which runs at right angles to the axis of compression, for the fracture passes always directly between the two compressed areas, modified only by the varying resistance offered to it in its transbasic course. In bilateral compression, also, a "bursting" fracture of the vault, the vault being the only "*convexity*," is never seen. If a vault fracture be present it is seen merely as a fissured fracture extending up from the region of the applied force and gradually tailing off towards the summit of the vertex. Further, I shall show that the lines of fracture proceed across the base always in the direction of the applied force, modified again only by the resistance offered by the stronger and weaker basic regions. These facts, and my own experience, render, in my opinion, the above theories quite untenable.

3. "*Contrecoup*" *theory*.—Fractures of the base alone are occasionally seen with direct evidence that the blow was received on the vault. Such cases have given rise to this theory which states that from the point struck a wave is transmitted through the semifluid brain, producing a fracture at some more distant point. Helferich, for instance, maintains that isolated fractures of the orbital roof, and more rarely of other parts of the base are produced by the influence of hydrostatic pressure. This theory is opposed to all experience in the mechanism of basic fractures and the peculiar fractures brought forward as examples are capable of a simpler explanation. The base being undoubtedly the weakest part of the skull fractures in this situation, when extending from the vault, frequently show greater comminution in the basic region than in the vault. A blow on the vault, therefore, may not suffice to produce a local fracture and yet the forces, when transmitted to any specially weak basic area, may there be strong enough to produce a fracture. Such specially weak basic areas are supplied by the orbital plates of the frontal bones and by the thin cerebellar fossa walls. In proof of this it is merely necessary to state that it is a common occurrence to find that as the result of a blow on the vertical frontal plate the orbital plates are comminuted, the vertical plate remaining uninjured, or at most the seat of a small fissured fracture. I show on the screen two cases, one a fracture of the cribriform plate of the ethmoid without any fracture of the vertical plate of the frontal bone, and the other a fracture of the posterior fossa which passed across the foramen magnum and tailed off on the dorsum ephippii, the resistance offered being too great. The forces, however, when conducted to the thin right orbital plate, still retained sufficient energy to produce a comminuted fracture in that region. It will here be in place to draw attention to the extreme friability of the orbital plates of the frontal bone, whilst the upward convexity of the orbital roof probably accounts for the fact that when that area is comminuted the fragments are practically always displaced upwards, the peri-orbital fat projecting through the gaps into the cranial cavity.

To arrive at any definite conclusions with regard to the mechanism of basic fractures it is necessary always (1) to take a careful history of the accident so as to determine in what manner the injury was received and also what part of the skull was struck; and (2) to compare the result obtained with all visible external signs of injury. A careful examination of a large number of cases of fractures of both vault and of base showed that in from 30 to 40 per cent. of cases the evidence was clear that the basic fracture resulted from, and extended from, a severe vault fracture. These cases are therefore examples of Aran's "irradiation" theory. This theory, however, further states that the fracture follows the shortest anatomical route to the base, whilst such is not the case, as (1) the line corresponds to the direction of the initial force, and (2) the line of fracture is markedly influenced by the resistance offered to it in its basic course, picking out, usually, all the weaker spots and avoiding the stronger, and it is only in the most severe cases that a fracture surmounts all obstacles and proceeds to the base directly in the line of the applied force. In over 60 per cent. of cases the injury was received (1) in front, over the lower frontal region, supra-orbital ridges, and external angular frontal process; (2) at the sides, over the auricular and mastoid region; and (3) at the back, over the region of the superior curved line of the occipital bone and the occipital protuberance. In all these cases, therefore, the injury was inflicted at or near the level of the base of the skull. The resultant fracture in all these cases was therefore a basic fracture by direct violence, the fracture passing inwards across the base and splitting the base in the same way as a chisel splits a board of wood, the grain of which may be regarded as representing the weaker lines and any intervening knot as representing the resistance offered by any strong bony buttress, momentarily turning aside the force which again later passes onwards, parallel to the original direction, but not necessarily in the same straight line. A blow in this region will tend primarily to involve the weaker area, the base, and secondarily to extend upwards on to the vault, many of the fractures in which situation result as extensions from blows delivered around the basic circumference. The statement, therefore, that all basic fractures result as extensions from the vault (Aran) is analogous to putting the cart before the horse, since many of these vault fractures result as extensions from the basic region.

There is still, however, another very important anatomical fact to consider and one which must necessarily exercise great influence on all basic fractures which result from falls or blows on the lateral aspect of the head and in most fractures produced by bilateral compression. The skull may be regarded as consisting of two parts, one part lying anterior to the condyles and the other posterior to, and including, the condyles, this latter part, owing to the vertebral attachment, being firm and fixed. As the result of a blow on the antero-lateral region of the head this anterior segment tends to be split off from the more fixed posterior part. If, again, in a fall from a height the post-mastoid region should strike the ground there is in that region a rebound force which acts in the opposite direction, whilst the anterior segment momentarily travels in the original direction; the two segments are consequently influenced for a brief period by forces acting in opposite directions with the inevitable result that they tend to be split one from the other. It is now necessary to point out that between the two segments there exist an exceedingly weak line, this line passing from one external auditory meatus to the other, involving in its course both middle ears, both petro-sphenoidal sutures, with the sphenoidal sinus as a connecting link in the middle line (Fig. 1). Such a fracture, as is indicated in the illustration, exemplifies a common and typical basic fracture and one which is most frequently seen when the accident is the result of a fall from a height. It is usual to find that the fracture extends up, on one or on both sides, on to the vault and occasionally this vault extension is so marked that the whole skull is practically divided into two parts, merely united by soft structures. More than once I have been able to elicit crepitus on the cadaver by rubbing the anterior and posterior segments together.

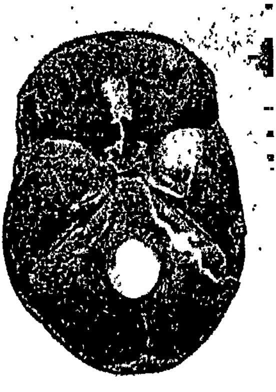
Collecting now the facts, so far as I have gone, I am of opinion: (1) that the bursting and compressing theory and the contrecoup theory are both untenable; (2) that Aran's irradiation theory, with certain modifications, accounts satisfactorily for those basic fractures which result from blows on the vertex; and (3) that most basic fractures result from forces applied directly around the basic level and that these fractures are the result of a splitting force, the line of fracture tending to travel across the base, parallel to the original direction, but not necessarily in the same straight line. It now remains to consider other factors which may exercise great influence on the actual direction of the fracture.

1. *The influence of sutures.*—Complete maceration of the skull is always necessary in estimating how far the various sutures of vault and base are affected in severe head injuries, for the dura mater, dipping down in these situations, usually completely obscures the lesion unless the degree of separation is marked. This injury is generally regarded as of rare occurrence and it is said by Morgagni to be most prevalent in the young. An examination of a large number of macerated skulls shows, however, (1) that separation along certain sutural lines is very common; (2) that this separation is most common in middle life; (3) that not only does

a suture tend to deaden a force, but if a suture lies in the path of a fracture, the forces tend preferably to follow that suture, even though the original direction may be slightly altered in so doing; (4) that in the more simple sutures the separation follows exactly the irregular sutural line, whilst in the more intricate sutures the line of separation passes along the suture, regardless of the finer dentations; and (5) that sutural separation, without any further basic lesion, is possible but of rare occurrence. The masto-occipital, petro-occipital, and lambdoid sutures are most commonly implicated.

2. *The influence of the air sinuses.*—(*a*) The sphenoidal sinus, formed by the hollowing out of the body of the sphenoid, varies greatly in size. In the great majority of cases it extends backwards nearly as far as the occipito-sphenoidal junction, whilst laterally it is separated by a thin plate of bone from the cavernous sinus. The roof and floor are usually paper-like in density, whilst the latter also assists in the formation of the naso-pharyngeal roof. The sinus, therefore, is bounded on all sides by a mere shell of bone and consequently there exists in the very centre of the base an exceedingly weak area, an area, therefore, which would naturally be involved in a very large proportion of all basic fractures. From my own experience this sinus was involved in 70 per cent. of cases, the comminution of roof and floor being in some cases so excessive that a large probe could be passed from the naso-pharynx into the cranial cavity so affording free means of ingress to micro-organisms (Fig. 2). Severe hæmorrhage may result from concomitant injury to the cavernous sinus and to the internal carotid artery, with furious bleeding into the naso-pharynx and nose. The illustration shows the great liability of the sinus region to injury, as (1) all fractures from one middle fossa to the other pass across the sinus (Fig. 1); (2) all fractures from one middle to the opposite anterior fossa also involve this region; and (3) most fractures of the anterior fossa or of the middle fossa tend to terminate in the sphenoidal body.

FIG. 2.



Showing an extensive fracture of the sphenoidal sinus.

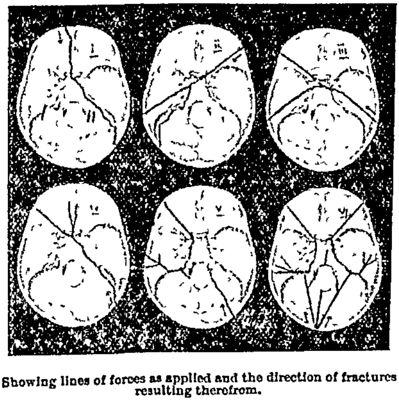
(*b*) Up to the age of puberty the frontal sinus is either absent or represented merely by a small air-cell, but after puberty it develops rapidly in size and extent. This fact is of importance in estimating the gravity of a fracture in the supra-orbital region at the different ages. The two sinuses are also generally asymmetrical and not infrequently the sinus extends far backwards into the orbital roof. The inner boundaries are often exceedingly thin and friable, whilst the outer wall consists of fairly dense bone, and consequently a fracture of the outer wall is almost invariably accompanied by a more severe and frequently comminuted fracture of the inner wall, or, in other words, by a fracture of the anterior fossa. The more prominent immediate resulting symptoms are: (1) hæmorrhage into the orbit and eyelids; (2) hæmorrhage into the nose; and (3) traumatic emphysema from the escape of air into the surrounding tissues, secondary to injudicious blowing of the nose, &c. The air in the cellular tissues may spread widely over the vault and face and into the retro- and peri-orbital tissues, with great swelling of the eyelids and proptosis of the eye. When localised the condition is known as "traumatic pneumatocele."

With regard to later complications it must be borne in mind that the more extensive fracture of the inner wall affords a mode of ingress for septic organisms with resultant extradural abscess or meningitis. It is therefore advisable when suppuration in the external wound occurs to chisel away or to trephine a portion of the outer limiting wall in the most dependent part in order to establish free and thorough drainage, the normal channel of exit into the middle meatus of the nose being usually blocked by swollen and lacerated mucous membrane or by blood clot. Unless some such treatment is adopted empyema of the sinus will probably result and death ensue from direct meningeal infection.

The auditory region.—I shall discuss later the great liability of this region to injury and will merely state here that this weakened area is involved in the great majority of middle fossa fractures. The exact lines of the fracture, the resultant hæmorrhage, the involvement of the seventh and eighth nerves, and other features will all be alluded to under their separate headings.

The basic foramina.—Battle, the only authority on skull fractures who enters into detail with regard to the influence of the foramina on the direction of a fracture, states that "the line of fracture is usually arrested if it meets with one of the foramina in its course, especially if the foramen be a large one." A careful examination of macerated skulls shows, however, that this view is erroneous; Fig. 1 illustrates three separate cases, chosen from numerous others, in which the fracture after reaching the margin of the foramen magnum was again continued on the other side of the foramen. The fracture, after traversing the thin cerebellar fossa, usually strikes the foramen magnum just posterior to the condyle [illegible] the opposite [illegible] the original [illegible] More rarely [illegible] continued on [illegible] is condition [illegible] ith two such cases, both of which are shown in the illustration. Turning from this foramen to others it is exceedingly common to find fractures traversing the foramen lacerum anterium, the foramen lacerum medium, or any other foramen that may lie in the chosen paths of basic fractures. Having now drawn attention to some of the more important anatomical features which exercise greater or lesser influence on the direction of a basic fracture, I will point out that by a careful comparison of the direction of the applied force and the point of application it is possible in the greater number of cases to arrive at conclusions guiding one in estimating the probable line of fracture in any given case (Fig. 3).

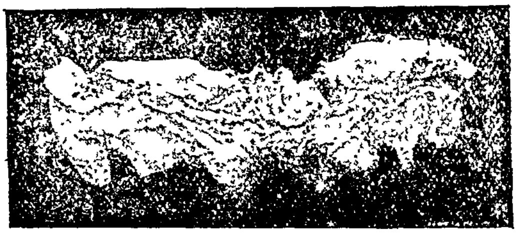
FIG. 3.



Showing lines of forces as applied and the direction of fractures resulting therefrom.

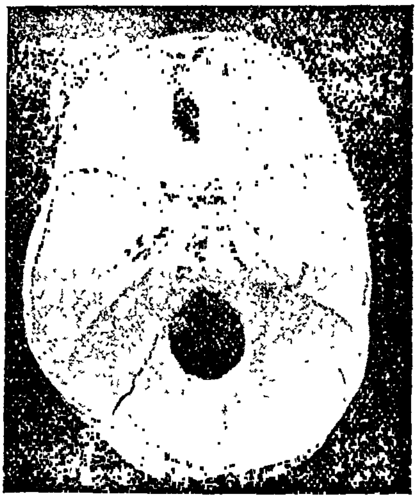
Direction, &c., of the Applied Force.	*Resultant Fracture.*
i. Force applied to median frontal region.	The fracture passes backwards from the perpendicular plate of the frontal bone to the cribriform plate of the ethmoid, thence between the optic foramina to the body of the sphenoid, the thin sinus roof being usually comminuted. From there the fracture diverges to the opposite side, and tearing off the posterior clinoid process passes along the petro-occipital suture to the jugular foramen, being again continued on the other side of that foramen along the masto-occipital suture, and so again to the vault.
ii. Force applied to the lateral frontal region, in the situation of the external angular frontal process.	The fracture passes across the anterior fossa towards the sphenoidal fissure, tearing away the anterior clinoid process, and again comminutes the roof of the sphenoidal sinus. Progressing onwards the posterior clinoid process is torn away and the fracture then passes either along the anterior part of the petrous bone at its junction with the greater wing of the sphenoid towards the opposite middle and external ears, or along the petro-occipital suture to the jugular foramen and continued along the masto-occipital suture, as in the previous case.
iii. Force applied to the region of the external ear.	The fracture passes across the roof of the bony auditory meatus towards the junction of the anterior and inner walls of the middle ear, the membrane and ossicles undergoing a varying amount of destruction and displacement. The fracture is then continued across the tegmen, which is in most cases more or less comminuted, and after following the region of the petro-sphenoidal suture it reaches the foramen lacerum medium, being continued again on the opposite side of that foramen to the sphenoidal body. Thence it pursues one of two courses. Most commonly the fracture passes obliquely backwards to the opposite middle and external ears, following a course similar to that already indicated. (Fig. 4.) In such cases the basic fracture may extend on each side up on to the vault in such a manner that the two segments are merely united by soft parts and an examination of the anterior aspect of the posterior fragment reveals further that the fracture passes just anterior to the geniculate ganglion of the facial nerve, which ganglion usually lies exposed. Its petrosal branches are, however, generally torn. The fracture also passes anterior to the Eustachian tube and anterior to the horizontal part of the internal carotid artery. In passing from without inwards, therefore, the following structures are to be noticed on the anterior aspect of the posterior fragment; the posterior half of the external auditory meatus, the mastoid antrum, the lacerated membrane and ossicles, the posterior two-thirds of the middle ear, the geniculate ganglion of the facial nerve, the Eustachian tube, the horizontal part of the internal carotid artery, the Gasserian ganglion, and the posterior part of the sphenoidal sinus in the middle line. After reaching the sphenoidal body, the alternative course for the fracture to pursue is to pass towards the opposite sphenoidal fissure, and tearing off the corresponding anterior clinoid process, to pass onwards across the anterior fossa, parallel to the original direction but not in the same straight line.
v. Force applied to the mastoid region.	The fracture follows the occipito-mastoid suture to the jugular foramen, and is again continued on the opposite side of this foramen, following the petro-occipital suture towards the apex of the petrous bone. Tearing off the posterior clinoid process, the fracture now passes across the sphenoidal body to the sphenoidal fissure of the opposite side, and so across the anterior fossa, parallel to the original direction. It is especially common in this particular variety of fracture to find fissures diverging from the region of the sphenoidal body forwards towards the cribriform plate the fissures passing mainly between the optic foramina and not usually directly involving those foramina. This fracture is also peculiar in so much that when the degree of separation along the occipito-mastoid suture is excessive there is a special liability to a tearing of the dura mater with injury to the sinus wall just as the sinus begins to dip downwards and inwards. (Fig. 2.)
v. Force applied to the lateral occipital region.	The fracture passes across the thin cerebellar wall, usually leading to some degree of comminution, and strikes the foramen magnum just posterior to the condyle, starting again at a similar position on the other side of the foramen and passing to the outer margin of the jugular foramen (Fig. 5). Two courses, again, are now available, for the fracture may either cut across the body of the petrous bone, external to the internal auditory meatus, finally comminuting the roof of the middle ear, or else the fracture may be continued from the inner part of the jugular foramen along the petro-occipital suture towards the apex of the petrous bone and the foramen lacerum medium. It usually then involves the corresponding sphenoidal fissure and passes across the anterior fossa, parallel to the original direction.
vi. Force applied to the posterior occipital region.	The resultant fracture varies according to the direction of the applied force. A force when applied to the posterior occipital region at right angles to the transverse axis of the skull results in a fracture which, on reaching the posterior margin of the foramen magnum, is continued on again on the opposite side of the foramen along the dorsum ephippii. When the force is more oblique in direction the fracture traverses the thin cerebellar fossæ to the outer margin of the jugular foramen and then follows one of the two courses indicated in the previous case. More commonly the fracture cuts across the petrous bone. An offshoot is frequently seen which passes to the foramen magnum just posterior to the condyles. The cerebellar wall is frequently comminuted and the lateral sinus may be torn in the line of the fracture.

FIG. 4.



Showing portion of the base of the skull with a fracture involving both auditory regions.

FIG. 5.



Showing fracture passing through cerebellar fossa.

Basic fractures, therefore, follow certain definite paths, the transbasic course varying according to the direction of the applied force and the point of application. These plans were worked out in the post-mortem room and were subsequently put to a practical use with the result that a correct diagnosis as to the path of the fracture was made in almost every case. It must be, however, clearly understood that the extent of the fracture, whether it completely traverses the base from side to side or not, depends on the amount of force used and the resistance offered, for bases, as well as vaults, vary greatly in density. To every rule also there must be exceptions and occasionally one may find some peculiar basic fracture which seems to follow no rule, whilst in other cases the force may be so excessive that the fracture crosses the base regardless of all obstacles. I venture to assert, however, that the lines of fracture indicated will in the great majority of cases be found to be correct. Finally, with regard to fractures produced by bilateral compression the line of fracture always tends to run between the two compressed areas, modified only by the relative strength of the intervening areas.

Fractures of the vault.—Fractures of the vault may be limited to that region or they may coexist with a basic fracture. Evidence has been brought forward under "fractures of the base" to show that in the latter class of cases the vault fracture frequently results as an extension upwards from the basic circumference. Whether, as the result of a blow on the vault, the fracture remains limited to that region or extends downwards also to the base depends mainly on the degree of force used and the direction in which that force is applied. The greater the force the greater is the tendency to vault limitation, whilst, on the other hand, a force applied obliquely downwards on to the skull surface usually results in an extension towards the basic area, not, however, following the shortest anatomical route to the base, as Aran indicated, but guided to the base by the direction of the applied force and by the resistance offered to it in its course. The fracture passes preferably between the various bony buttresses which pass up from base to vault, except in those cases where, owing to greater violence, it passes to its termination regardless of the obstructions which may lie in the path. Lastly, fractures of the vault, produced by falls from a height on to the summit or on to the side of the head, are usually complicated by a concomitant basic fracture, the weight of the falling body being transmitted through the condyles, greatly influencing the extent and direction of the forces acting. The varieties of vault fracture are of such text-book prominence that I propose to confine myself to three points only.

1. *Fractures of the external table.*—The possibility of a fracture of the external table without any injury to the internal table was up to recent years a matter for dispute. The late war in South Africa has, however, conclusively proved the existence of such a fracture. This "gutter-shaped" fracture usually results from a glancing or spent bullet. Such fractures are, nevertheless, of such rare occurrence and of such difficult diagnosis that they form no exception to the rule that exploration and trephining should be carried out when there is any suspicion that a more extensive injury to the internal table may also be present.

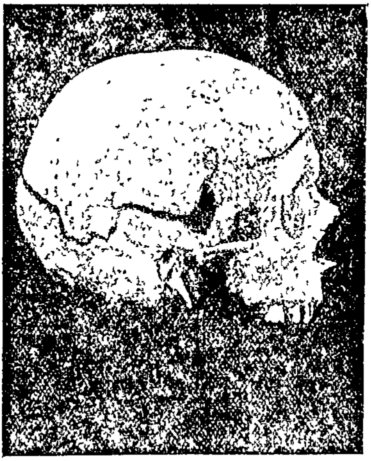
2. *Fractures of the internal table.*—"When a foreign body passes completely through any part of the skull—it matters not what the direction may be—the aperture of exit is always larger than the aperture of entry." Such was the law enunciated by Teevan in 1864 and explained by him as follows: "The aperture of entry is caused by the penetrating body only, whilst the aperture of exit is larger, inasmuch as it is made by the penetrating body plus the fragments of bone driven out of the proximal table and diploe." Previously to this theory the explanation offered was that the internal table was the more brittle Teevan proved that this was not the case as by firing a bullet from inside the skull the wound of exit was again greater than the wound of entry. It was also proved that whether the inside or the outside of a skull be struck fracture of the distal table only, without any injury to the proximal table, can be produced in either case. This is, as Teevan pointed out, in obedience to the law that "when pressure is applied to a body, when it breaks the fracture commences on the line of extension, not that of compression." Fractures of the internal table are most common and most extensive in those regions where the diploic tissue is most abundant—e.g., the mid-parietal and anterior frontal regions. Too much stress, therefore, cannot be laid on the fact that (1) fractures of the internal table only may exist without any visible or palpable injury to the external table; and (2) that when the external table is fractured there is in nearly every case a more extensive fracture of the internal table. The depressed internal table may give rise to many complications, of which the following are the more important.

(1) *Immediate.*	(2) *Remote.*
A. Injury to the membranes, venous sinuses, and meningeal arteries.	*A.* Meningeal thickening, chronic cerebritis, and arachnoid cysts, with consequent localised cephalalgia, Jacksonian epilepsy, and insanity.
B. Injury to the brain substance	*B.* Meningitis, cerebral abscess, &c. (when compound).

Some of the complications and the question of treatment will be alluded to later.

3. *Explosive fractures.*—The passage of a bullet through the brain leads occasionally to such intracranial disturbance of the fluid and more solid contents that the resultant explosive force, combined with the forces acting on the skull from the impact of the bullet, produces a peculiar fracture which I may call an "explosive fracture." More commonly the sutures give way, especially along the line of the sagittal suture, but in more rare cases the vault may be more or less completely lifted off from the base. This unique specimen which I show you is an example of this latter variety. The bullet, fired from a pistol held close to the right temporal region, passed through the brain and impinged against the opposite parietal region, producing an "elevated" *fracture, the external table being more extensively damaged than the internal.* In spite of an abnormally massive skull an irregular fracture extended completely round the skull, except for about two and a half inches in the right occipital region, lifting the vault from the base like a trap-door. There was no basic fracture. (Fig. 6.)

FIG. 6.



Explosive fracture caused by a pistol shot in the right temporal region.

Fractures in children.—In comparing a child's skull with that of the adult it can at once be seen that there are certain peculiarities in the former which must influence the direction and the extent of a fracture. 1. The bones of the vault are elastic and pliable and consequently a blow may lead to a bending-in, temporary or permanent, without any actual fracture. Dense fibrous tissue also intervenes between the bones, tending to limit the fracture to the bone struck, extensions to the basic regions being comparatively rare. 2. The diploic tissue is practically absent and consequently fractures of the internal or external tables only are almost unknown. 3 The air sinuses are non-existent or small. It is especially important to bear this in mind in estimating the gravity of severe fractures in the anterior frontal region. The greater adherence of the dura mater in the child is said to prevent the formation of any extensive extradural clot. There can be no question that middle meningeal hæmorrhage in children is rare, but I put this down, not to the supposed greater adherence of the dura mater, but to the fact that, owing to the elasticity of the skull and the absence of bony spicules from the internal table, the artery usually escapes laceration, being more commonly pushed aside or compressed. Bruising and superficial laceration of the brain are, however, relatively more common in children than in adults, owing to the greater delicacy in structure of the arachnoid, pia mater, and cortex. A comparatively slight blow leads consequently to subpial and subarachnoid hæmorrhages, resulting in violent convulsions when situated over the Rolandic area.

of the base, though obviously of less frequent occurrence, in their direction and extent follow the rules already put forward under "fractures in adults." The presence of the petro squamous suture makes more grave the prognosis of a fracture, involving the middle ear and being followed by suppuration.

Relative frequency of fractures of the anterior, middle, and posterior fossæ.—A basic fracture may be limited to one fossa only or all three may be involved at one and the same time, whilst in rare cases the anterior and posterior fossæ may be fractured, the intervening middle fossa remaining uninjured. Fractures implicating the anterior and middle fossæ are almost invariably accompanied by definite symptoms, rendering the diagnosis fairly certain, whilst fractures of the posterior fossa are frequently overlooked owing to the absence of definite clinical symptoms, and it is of common occurrence to find at the post-mortem examination a fracture in this situation the existence of which had not previously been suspected It is probable that fractures of the middle fossa are the most common and fractures of the posterior fossa the most rare.

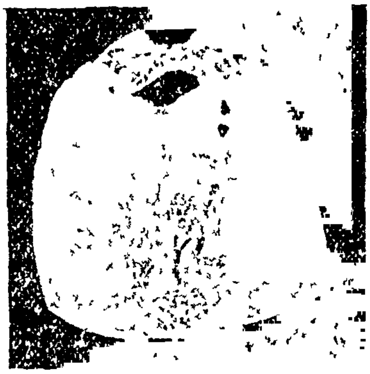
Mortality according to the fossa implicated —In endeavouring to estimate the mortality according to the fossa implicated the same difficulties arise owing to the uncertainty of the diagnosis of posterior fossa fractures. There are, first of all, dangers peculiar to each fossa. 1. Anterior. Septic infection from the nose, ethmoid cells, &c. 2 Middle. Septic infection from the naso-pharynx and ear, injury to the middle meningeal and internal carotid arteries. 3. Posterior. Injury to the venous sinuses Fractures of the middle fossa, therefore, are the most dangerous from local complications There is, however, a grave complication which is common to all fossæ, injury to the brain itself, and since the vital centres are grouped posteriorly in the region of the fourth ventricle the prognosis of fractures of the posterior fossa is correspondingly rendered more grave. Probably the mortality increases from before backwards, fractures of the anterior fossa being certainly the least dangerous, with but little to choose between a fracture involving the middle fossa and one implicating the posterior fossa. The general mortality as given by different authorities does not vary very much. Battle from 168 cases puts the general mortality at 32 per cent. This is, according to my experience, too low, for in 215 cases 89 died and 116 recovered. The mortality equalled 44 *p*er cent. Fractures of the base occur at all ages of life, the death-rate being highest at the two extremes of life, from 50 to 60 per cent under the age of five years, and from 60 to 70 per cent after the age of 70 years.

Mortality of vault fractures, with and without depression.—The general mortality of vault fractures, with or without depression, is from 20 to 25 per cent., the death-rate now being lowest in children and highest in old age.

There are still some surgeons who refuse to believe that a patient can recover from a severe basic fracture. Clinical experience, however, shows again and again that even after the most extensive injuries patients may completely recover, and this is especially the case in young adults. As an example I will briefly narrate one case. A boy, aged 15 years, was hanging by his feet from a wharf when a barge, swinging inwards, crushed his head against one of the piles. When admitted he was collapsed and pulseless and bleeding profusely from both ears, from the nose, and from the mouth Both tympanic membranes were lacerated at the upper and anterior part and subsequently marked facial paralysis was seen on one side. One pupil was widely dilated and the other was contracted to a pin-point, and added to this there was marked internal strabismus of one eye with proptosis. In spite of all these troubles the boy made a rapid recovery, all symptoms disappearing except the squint. A more typical picture one could not desire and the symptoms all indicated one of the most severe basic fractures—that fracture which I call "the typical basic fracture"—as it undoubtedly passed from one auditory meatus to the other (Fig 4), involving both middle ears and the sphenoidal sinus in the middle line. The line of fracture passed just in front of the genu of one facial nerve and from the sphenoidal region there was an extension forwards to the sphenoidal fissure, thus accounting for the orbital symptoms. The sixth nerve was probably injured, as it laterally grooves the dorsum ephippii and, as I shall point out under "nerve implication," injuries of the sixth nerve in that situation frequently lead to a permanent paralysis.

Though there are but few who refuse to believe in the possibility of recovery in such cases, yet there are many who regard a posterior fossa fracture as necessarily fatal. Such a view is hard to refute by a mere recitation of cases, since these fractures are conspicuous by their lack of clinical symptoms. The illustration, however, is that of a united fracture of the posterior fossa and it exemplifies well certain peculiarities common to all united basic fractures (Fig. 7). The new bone formation is poor in quality and in quantity, being rough and porous, and almost limited to the inner aspect of the skull. On the outside the fissure remains quite definite, the edges being slightly rounded off with scattered bridges of new bone formation. The dura mater is generally firmly adherent to the rough new bone and also thickened and discoloured.

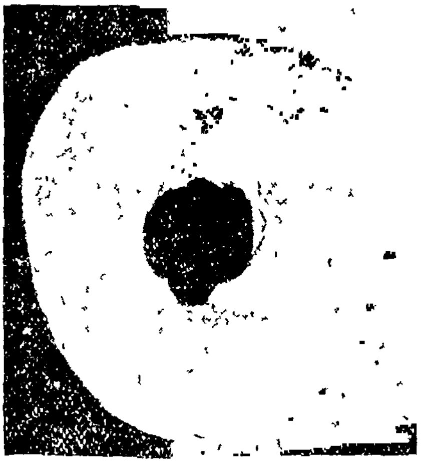
FIG. 7.



A united fracture of the base of the skull.

The medico-legal aspect of skull fractures.—The next illustration is of great interest on account of its medico-legal importance. The man from whom the specimen was obtained was seen by several witnesses to commit suicide in a state of suicidal frenzy by striking himself repeatedly on the vertex of the skull with a dumb bell. The evidence of repeated blows is borne out by the appearance of the vault. A central hole, nearly circular in shape, is surrounded by numerous semicircular dents and fissures, showing that several blows were inflicted (Fig. 8) Those fragments which were not driven into the brain were torn out by the patient before he became unconscious. The greater destruction of the internal table is also of interest. The position of the fracture, the evidence of repeated blows, and the nature of the implement used would in the absence of reliable witnesses have been sufficient to lead to a verdict of "wilful murder."

FIG 8



A fracture of the vertex of the skull from repeated blows.

Two other cases of equal medico-legal interest are reported by Mr. R. Withers of Plymouth. The first case was that of a man who was admitted into the Tuapeka Goldfields Hospital, New Zealand, 25 years ago, suffering from a comminuted fracture of the frontal bone, exposing the dura mater. He was found unconscious in a hut with a blood-stained tomahawk lying by his side. His mate was arrested, but fortunately for him the injured man recovered consciousness after [illegible] Having collected [illegible] mate to get stores [illegible] nt the money in a prolonged debauch and on his way home an angel appeared to him and pointed out to him the iniquity of his conduct in thus defrauding his mate. In consequence of this and in order to expiate his offence, on his arrival at the hut he knelt down on the floor and proceeded to smash in his forehead with the butt end of the tomahawk, continuing his efforts till he lost consciousness.

The second case was that of a Kanaka on a sugar estate in Australia. This man was found lying in the hut of another Kanaka with his forehead crushed in and a hatchet beside his body. He remained insensible for several days but eventually recovered and stated then that his injuries were self-inflicted and that he went to the other man's hut so that suspicion of murder should rest upon him.

ON THE USE OF DR. MARMOREK'S ANTITUBERCULOUS SERUM.

BY ARTHUR LATHAM, M.A., M.D. OXON.,

ASSISTANT PHYSICIAN AND LECTURER ON PRACTICAL MEDICINE AT ST. GEORGE'S HOSPITAL; ASSISTANT PHYSICIAN AT THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

EARLY in December last I was so much impressed by Dr. Marmorek's arguments against tuberculin being the real toxin in tuberculosis and by the value of his evidence that the new toxin, by means of which his antitoxic serum is prepared, is the true toxin, that I asked him for a supply of this serum in order that I might investigate its value upon selected cases at St. George's Hospital and at the Brompton Hospital for Consumption. Dr. Marmorek not only gave me a free supply of the serum but came over from Paris on three occasions in order that I might have the benefit of his advice.

At the commencement of this investigation Dr. Marmorek expressly stipulated that the serum should only be given to severe or to urgent examples of the disease. "If," he said, "you find in these cases, as I have found, that the serum does no harm, and still more if you find you are able to ameliorate the symptoms and diminish the extent of the disease, then you will be justified in extending your investigation to cases in which the disease is less severe and in which the prognosis is more hopeful." This unusual attitude was no doubt the most scientific one to adopt but it necessarily somewhat increased the difficulties with which one has to contend in an investigation of this kind. My experience is limited to some 30 severe cases and extends over a period of three months; consequently it is premature for me to give a decided opinion as to the value of the serum. I have, however, gladly consented, in deference to Dr. Marmorek's express wish, to give the general impressions I have formed of this new treatment up to the present time. And although I cannot bring forward any indisputable evidence that the serum is capable of producing what is termed a cure of tuberculosis my experience of the necessary technique, of the dosage and action of the serum, and of the complications which sometimes occur, may be of value to the profession at the present moment, for there can be little doubt that, in virtue of the paper recently read by Dr. Marmorek at St. George's Hospital,[1] an extended trial of the value of the serum will now be made in this country.

The difficulties of forming a trustworthy judgment in the investigation of a new remedy in a disease which presents such a changing picture as tuberculosis must be borne in mind. In the first place, we have not much experience of the effects of horse serum when it is used during a period of several months. Consequently, we are, to a certain extent, ignorant of the effects which should be properly attributed to the serum and not to the antitoxin. There is in addition the difficulty which is always present in the treatment of tuberculosis, the difficulty experienced in differentiating between *post* and *propter*, when we try to estimate the value of our remedy. For example, two patients to whom I refused the serum developed pneumothorax within a week and rapidly succumbed. In another case, in which I postponed my decision, there was an acute exacerbation of the disease a few days later with a fatal result. In another instance Dr. Marmorek put off the first injection from a Saturday to the following Monday; the patient, however, succumbed to profuse hæmoptysis on the intervening Sunday. In all these cases if the serum had been used an adverse judgment of its value might have been formed. Again, no one who has not had an experience of this kind can realise the difficulty there is in obtaining suitable cases when one wishes for them. Naturally, all my patients had the treatment explained to them and were asked for their full consent. A proportion of patients refused their consent; others who consented would not persist with the treatment for a reasonable time. Others again could not support the serum. Finally, there was the difficulty of determining the general technique and the most suitable dose of the serum.

THE TECHNIQUE.

The serum is injected under the skin. As a rule I have injected it into the abdominal wall; some patients, however, prefer to have the injections made under the skin of the back, of the axilla, or, in the case of men, of the arm. In surgical cases it is possible that the serum may be more beneficial when injected somewhere in the neighbourhood of the lesion. For the first injection the skin is prepared as if for a surgical operation and the puncture made by the needle is closed with collodion. If an extensive preparation of this kind is made for each injection the skin soon becomes sensitive. Consequently, after the first injection we have covered the selected area with cyanide gauze and then for each subsequent injection contented ourselves with swabbing the skin with some antiseptic before using the needle. That this procedure is sufficient is shown by the fact that no sepsis of any kind has followed the injections given in the cases which have been under my care. These injections amount to over 450 in number. Successive injections should not be made in the immediate neighbourhood of previous ones. Too much collodion should not be used in closing the puncture made by the needle as this substance may set up some irritation of the skin. The syringe and needle are naturally sterilised before use, preferably in an autoclave. I employ a separate needle for each case and have each needle thoroughly sharpened every day before sterilisation. This is an important point for the comfort of the patients in a long series of injections.

The serum is supplied in bottles of varying size and it frequently happens that some serum is left in the bottle after the required amount has been withdrawn. In order to prevent the contamination of this the following procedure is adopted. The cork and the neck of the bottle are sterilised by being passed through a spirit flame; the cork is then withdrawn by pressing it to one side and not by a revolving or corkscrew action. The required amount of serum is drawn into the syringe; the cork and the neck of the bottle are again sterilised and the cork is reinserted. The serum should be kept in a cool place but not on ice. If the serum becomes cloudy or if it is definitely blood-stained it should not be used. Dr. Marmorek prefers to give the serum in the morning between 9 and 11 o'clock.

With regard to the dose, in chronic cases we at first gave ten cubic centimetres every day for seven, eight, or nine days. This series of injections was followed by a period of intermission lasting a week or ten days. At the end of this period the serum was given in five cubic centimetre doses for two days and in six cubic centimetre doses for a further two days. After one day of intermission seven cubic centimetre doses were now given on two days. Eight cubic centimetres were given on the next day, and nine cubic centimetres on the final day of this series. A further week or ten days were allowed to elapse and a third series similar to the second was then given, and so on. These doses, however, were too large and too frequently led to serum effects. We now use five cubic centimetre doses for four consecutive days, followed by a period of three days' rest. A second and third series are then given of the same dose and with the same period of intermission. When the third series has been given the next period of intermission should in most cases last at least two weeks. My later experience tends to show that patients sometimes begin to improve during these periods of intermission, whilst they may show no improvement if the serum is pressed too hard. No definite rule can be laid down, however, in this matter as individuals show such a varying capacity for supporting the serum. Some patients have received a large amount of serum in a comparatively short period of time and have shown no serum reaction whatever—such as rashes, tenderness, enlargement of glands—whilst others are unable to support three consecutive doses of five cubic centimetres Some cases can only support the treatment when the injections are given every other or every third day. The main thing to watch in fixing the dosage for a particular case is the capacity of the individual to support the serum. In all cases it is important to have periods during which the use of the serum is discontinued. These periods of intermission, again, must vary in individual patients. For example, if a patient shows definite serum effects such as a rash, &c., after four days' injection the period of intermission should be longer than in a case in which a patient shows no such reaction.

---

[1] THE LANCET, March 26th, 1904, p. 854.

In acute cases and, as far as my experience goes, possibly in surgical cases larger doses may be given. In acute disease, such as meningitis, as much as 30 cubic centimetres in divided doses may be given every day for four or five days, the dose being then gradually diminished. I have given a child five years of age 30 cubic centimetre doses for four days without harm. In adult surgical cases from eight cubic centimetre to ten cubic centimetre doses appear to be frequently well borne.

Serum Effects.

By these I mean certain results which may be attributed to the horse serum and not to the antitoxin. A certain proportion of individuals are unable to support this serum just as others, even healthy men, are unable to support antistreptococcic or plague serum. In such cases there may be a rise of temperature, a feeling of malaise, some tenderness about the seat of injection, enlargement and tenderness of the neighbouring glands, neuralgic pains, development of various rashes, and, in rare instances, affections of the joints. In every case if the dose of serum is pushed too far these phenomena, or some of them, may present themselves. In many instances 10 cubic-centimetre doses cause a rise of temperature in chronic cases. The temperature usually falls again when the injections are omitted. In certain instances this rise of temperature does not occur until after the injections have been discontinued, showing a certain cumulative effect of the serum. In two cases this rise of temperature has persisted for some weeks. It may be said that in both these instances the serum did harm. One of these cases was converted from the apyrexial type to the pyrexial type. In this case blood-stained serum was given and this I have now learnt should never be employed. In the other case, which was one of great severity, the patient supported the serum badly and we used what we now know to have been too large doses. Now that we use smaller doses we meet with this rise of temperature exceptionally and not to the same extent. If such a rise of temperature (to from 101° to 103° F.) occurs, then, in view of my experience, the use of the serum must be stopped and only tentatively renewed some days after the temperature has declined. By carefully watching the temperature it is sometimes possible to anticipate the cumulative action of the serum. When this occurs the injections should be temporarily suspended.

The rashes which make their appearance are the ordinary serum rashes—i.e., urticaria, erythema, and scarlatiniform eruptions. These may occur after three or four injections and are most common after eight or nine consecutive injections. They may occur within a few hours of an injection or they may occur some days after the injections have ceased. The commonest is an erythema about the seat of injection which as a rule may be neglected, save as a signal that the series of injections may soon have to be interrupted. When there is a general erythema or urticaria with coryza and a rise of temperature the injection must be omitted for a varying period, usually for a week. In some instances of this kind there is but little feeling of malaise and in yet others, although the temperature is appreciably raised, there is little alteration in the number of pulse beats or of respirations. In some cases, simultaneously with the rash, the patient suffers from a feeling of "pins and needles" in the limbs; this sensation may be followed by definite neuralgic pains. In one case there were swelling and tenderness of one of the finger-joints; this, however, lasted only three days. In a certain proportion of cases, more especially when the injections have been numerous, there is considerable œdema at the seat of injection. The œdema may be quite hard, is sometimes painful, and may last for a considerable time; in many instances, especially if there is no pain, this condition need not cause the injections to be interrupted.

Again, in three instances in which I gave doses of ten cubic centimetres for some time at the commencement of this investigation the patients became drowsy and listless. These symptoms pass off as soon as the serum is discontinued. In two or three instances there has been a certain amount of vaso-motor disturbance a few minutes after the injection and one patient fainted and became collapsed after the nineteenth injection of five cubic centimetres of the serum.

The Antitoxic Effects of the Serum.

As I have already said, my experience is not yet sufficient to justify me in giving any definite opinion on this point. It is, however, already clear that the serum has its limitations. We cannot expect to obtain any permanent relief by its use in a large number of cases in which there is extensive disease of some years' standing or in cases in which there are marked excavation and secondary infection. In some instances of this class of case which I have treated the disease has made steady progress during the time the injections have been given. In the majority of instances, however, my patients have expressed a definite opinion that they feel more comfortable for the injections. In three cases out of the six treated of surgical tuberculosis the pain and tenderness disappeared completely after a few injections had been given. In the majority of cases of pulmonary tuberculosis the first few injections lead to an increase in the weight of the expectoration and to an increase in the number of moist sounds. In a certain number this increase has been followed by a diminution in the weight of the sputum which has been progressive, together with a diminution in the number of adventitious sounds. These results are sometimes more marked during the periods in which the injections are omitted than they are when the serum is being used. It is too early, however, for me to give a useful summary of the effects of the serum on the various symptoms, especially as a considerable proportion of the comparatively small number of cases I have had an opportunity of treating for an adequate period are still under treatment. I will content myself with giving a few examples of the cases under my care which appear to show that the serum does produce a definite antitoxic effect.

Case 1.—The patient was a male, aged 19 years. Five weeks before admission he had consulted Dr. E. C. Greenwood who sent him to me. For two weeks previously to his visit to Dr. Greenwood he had been feeling "out of sorts" in consequence of a strain at football. Up to this time he had always felt well. For the last three weeks before admission he had suffered from cough, night sweats, and fever. During the last month he had lost six pounds. On admission he was anæmic and complained of dyspnœa on exertion and of being easily fatigued. The pulse was 108, regular, soft, and of poor volume. The evening temperature was 100° F. On examination it was found that there was tuberculous infiltration throughout the right lung with signs of commencing softening in the upper third. The left lung was healthy. During the first week in the hospital, when no injections were given, the average daily weight of the sputum, which was nummular and muco-purulent in character, was one ounce. The sputum contained on an average 38 tubercle bacilli in the film. The body-weight was 9 stones 6 pounds. This patient received 145 cubic centimetres of the serum in 23 injections. After six weeks' treatment he left St. George's Hospital for the Royal Ventnor Hospital. During his treatment he became stronger and felt much more comfortable. The night sweats ceased and the cough became less troublesome. The amount of expectoration became less and instead of averaging, as on admission, one ounce by weight a day averaged 2½ drachms. The number of tubercle bacilli showed *no diminution*. The patient, who was of a better class than the usual hospital patient, gained ten pounds in six weeks. When he left St. George's Hospital he was able to walk three miles without fatigue. The temperature became practically normal. The dyspnœa disappeared. With regard to the physical signs it is interesting to record that there was no extension of the disease to the left lung. The actual extent of the disease in the right lung [illegible] the six weeks of treatment. [illegible] ·en signs of softening there [illegible] ith comparatively few moist sounds. In the rest of the right lung the adventitious sounds became markedly less.

CASE 2.—The patient was a man, aged 36 years, who was treated at the Brompton Hospital. In July, 1903, he had an attack of hæmoptysis. Since then he had suffered from cough and expectoration. On admission he was described as a fairly healthy man with a malar flush. His voice was hoarse, the epiglottis was thickened and rigid, and no view of the larynx could be obtained. The evening temperature was 101° F. The daily weight of the sputum varied from three to six ounces and contained tubercle bacilli. The body weight was 9 stones 6 pounds. The whole of the left lung was found to be infiltrated and there were large crepitant râles to be heard in the region of the axilla and over the lower half of the lung. This patient has had up to the present time 260 cubic centimetres of the serum in 42 injections. At first he felt more comfortable and the night sweats disappeared. After three injections the evening temperature fell from 101° to normal, although a week's treatment under ordinary conditions had produced no change in his symptoms. After 42 days' treatment the physical signs in the left lung had somewhat diminished, the large crepitant râles being less numerous, but there were now signs of early infiltration at the apex of the right lung. Consequently the serum treatment was omitted on Jan. 22nd. The evening temperature, which hitherto had been normal except at the commencement of the treatment, again rose to 100° on Feb 6th and remained at this point till the 18th. The man began to lose ground. At his own request the injections were renewed on the 16th and the temperature again became normal on the 18th. At the present time the physical signs in his left lung, more especially at the base, are much less marked as far as adventitious sounds are concerned and the recent infiltration at the right apex shows signs of diminution. The voice is distinctly less hoarse, the general condition is improved, and there has been a gain in weight of 11 pounds in three and a half months. The weight of sputum and the number of bacilli so far show no sign of decrease.

CASE 3.—The patient was a male, aged 17 years. He had a chill 12 months before admission to the hospital with subsequent cough. He had been losing ground for the last three months. On admission he was suffering from night sweats and dyspnœa. P[illegible] l infiltration of the upper third [illegible] excavation on the left side. 1[illegible] um were given in 26 injections. The patient has left the hospital with his general condition somewhat improved in that he has lost his night sweats and suffers less from dyspnœa. His weight has remained stationary and the physical signs in the lungs show no alteration beyond some diminution in the number of moist sounds. The interest of this case lies in the sputum. This, though never profuse, showed a diminution in weight. Again, during the first week of treatment 40 tubercle bacilli were found in the average field together with a few elastic fibres. During the last eight weeks of the patient's stay in the hospital a weekly examination of the sputum failed to reveal any elastic fibres or tubercle bacilli except a clump of four bacilli on one occasion. The sputum contained a number of cocci and towards the end of the treatment was possibly largely pharyngeal

CASE 4.—This case was one of extremely acute tuberculosis. A woman under the care of Mr. Owen Lankester, who had previously enjoyed good health, complained of feeling unwell. On an examination of the chest crepitations were discovered at the apex of the right lung. Tubercle bacilli were present in the sputum. The disease rapidly spread throughout both lungs and a fatal issue resulted in six weeks from the onset of the first symptoms. When I saw this patient five weeks after the commencement of the illness there appeared to be no hope whatever of a favourable issue. Large crepitant râles were heard over the entire surface of both lungs. Dyspnœa was marked, the pulse was feeble, and the temperature was 105° F. In view of my limited experience of the serum at that time I was not anxious to try it in this case, but somewhat against my will consented to do so. The effect of the serum, which was given in doses of five cubic centimetres, was well shown in the temperature chart. Not only was the temperature reduced but the character of the daily curve was altered. The clinical records extended over 11 days—namely, from Feb. 4th to the 14th—the temperatures being taken every four hours. On nine occasions the maximum daily temperature was at 2 A.M. or 6 A.M., while on two occasions it was at 10 A.M. or 2 P.M. Injections of five cubic centimetres of serum were given on Feb. 7th, 8th, 9th, 10th, 12th, 13th, and 14th. On and after Feb. 9th the character of the temperature curve was changed, the daily maximum being lowered and the fluctuations greatly reduced in their range. On Feb. 9th the maximum recorded was 103° and the minimum 101°. On Feb. 10th the maximum was 101·6° and the minimum 99·6°. On Feb. 11th, when no injection was given, the maximum was 103° and the minimum 98·4°. On Feb. 12th the maximum was 101° and the minimum 97 6°. On Feb. 13th the maximum was 100 4° and the minimum 97 8°. On Feb. 14th, when death took place in the evening, the maximum was 100°. The highest recorded pulse-rate was 108 and the lowest was 80. The condition of the lungs showed no amelioration. I gave the small doses of five cubic centimetres partly because I did not wish to set up unpleasant serum effects and so to add to the discomfort of the patient, but chiefly because I thought that the serum, which, as I have said, often increases the amount of expectoration and the number of adventitious sounds for the first few days, might act detrimentally if given in large doses in this case on account of the severity of the catarrh already present. It is an open question whether large doses should not be given in a similar case. Certainly, if a case of this kind is seen at an earlier period, doses of at least ten cubic centimetres daily should be given.

CASE 5.—The patient, a boy, aged 14 years, was sent into St. George's Hospital by Mr. T. Crisp English for early tuberculosis of the lower end of the fibula on the left side. There was a history of aching pain in the left ankle for 14 days. No cause of the disease was known and there was no history of an injury. A swelling had appeared after a few days. On admission there was definite thickening of the lower end of the left fibula. The skin over the outer malleolus was livid and glossy. The movements of the ankle-joint were fairly free but there was pain on pressure and on extreme extension. The tibia was unaffected. The boy was kept in bed but received no treatment beyond the injections of serum. 55 cubic centimetres of serum in six injections were given. After three injections the pain completely disappeared and 14 days after the commencement of the treatment the condition of the boy was such that he was allowed to get up and to walk about the ward. The disease apparently has been completely arrested. This case is the only example of early tuberculosis which I have treated so far with the serum. It is, of course, in no way conclusive, for such cases show improvement sometimes of a similar kind when treated with rest alone. The rapid disappearance of the pain and subsidence of all symptoms are, however, suggestive.

As a result of my experience of this new treatment up to the present time I think I may say that the serum when given in carefully graduated doses, with proper precautions and in suitable cases, does no harm. Further, my experience tends to show that the serum does produce a specific antitoxic effect. In any case, there can be no doubt that an extended trial of this remedy should be made, more especially in less severe cases than those to which I have hitherto intentionally confined my attention. It must not, however, be forgotten that great care must be exercised in the administration of this remedy and that the treatment may have to be extended over a considerable time before permanent results are obtained.

In conclusion, I would express my gratitude to Dr. Marmorek for his advice and constant consideration, to a number of my colleagues for their kindly coöperation, to Dr. W. B. Swete Evans of St. George's Hospital, and to the house officers of the Brompton Hospital for their unwearying assistance.

Brook street, W.

HOSPITAL SUNDAY FUND IN BRISTOL.—Up to March 10th 359 collections in aid of the Lord Mayor of Bristol's Hospital Sunday Fund, yielding £1700, had been received. The number made in 1903 was 327, producing £1565, and this year's collections have exceeded that total by £135.

THE MENTAL CONDITION IN EPILEPSY IN RELATION TO PROGNOSIS.[1]

BY WILLIAM ALDREN TURNER, M.D. EDIN., F.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS AT THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, AND AT KING'S COLLEGE HOSPITAL; AND VISITING PHYSICIAN TO THE COLONY FOR EPILEPTICS, CHALFONT ST. PETER.

IN a previous communication to this society[2] I dealt in general terms with the prognosis and curability of epilepsy, with reference more particularly to the convulsive element. In the present paper a special study has been made of the influence of the mental condition in epilepsy upon the prognosis of the disease.

That the mental condition in epilepsy has been the subject of much investigation is apparent from a review of most of the treatises upon the disease. Morel speaks of the "epileptic character" and other writers refer to the characteristic loss of memory and irritability of temper shown by many epileptics. Reference is also not uncommonly made to epileptic insanity, but authorities differ as to the frequency and causation of a disordered mental state. Whether, indeed, it is an essential feature of the disease, whether epileptics tend invariably towards dementia as a natural consequence of the malady, or whether it is dependent upon the frequency, the character, or the severity of the seizures, is the subject which will now be brought under discussion.

A brief reference may first be made to the proportion of epileptics who become mentally afflicted according to the statements of different writers. Esquirol,[3] for instance, stated that of 385 epileptic women observed in the Salpêtrière, 73 per cent. were mentally afflicted. Russell Reynolds[4] referred to the fact that of the 62 cases studied by himself, 38 per cent. were free from any mental failure, 46 per cent. showed some degree of mental impairment, and 14 per cent. were demented. Wildermuth[5] mentioned that the percentage varied according to whether the cases were observed inside or outside an institution. From the observation of his institutional cases he found 78 per cent., and of those outside the institution 47 per cent. mentally afflicted. Habermaas,[6] who has studied the mental condition in detail amongst the patients attending the Epileptic Institute at Stettin, gives the following figures: 17·3 per cent. were intellectually normal, 21 per cent were able to earn wages, 30 per cent. could do some work, and 49 per cent. were so demented that they were unable to work at all. Of those patients who were inmates of the institution only 13 per cent. were intellectually normal and 22 per cent. were demented, while the remainder showed intermediate degrees of mental failure. Some further facts mentioned by Habermaas may be added. He refers to Tigges, who found 23 per cent. out of 124 epileptic children mentally defective, and to Pelman, who found 50 8 per cent. of epileptics mentally healthy. The above-mentioned facts show that in the opinion of many writers upon epilepsy mental failure is more common than mental health and that this is true whether the patients are observed inside or outside an institution for epileptics.

THE MENTAL CONDITION IN EPILEPSY.

The mental state in epilepsy is usually described under two heads: first, that which may be regarded as incidental to the seizures; and, secondly, the interparoxysmal condition. The former heading includes all those delusional, maniacal, and melancholic states which precede or succeed more especially the major convulsions and which may be considered as constituting epileptic insanity, while the latter embraces the mental attitude and characteristics of the patient between the seizures, and may with confidence be looked upon as the typical epileptic mental condition. It is therefore the latter element of the disease which will receive detailed consideration in the following remarks.

Following upon the lines laid down by Reynolds, Habermaas, and others, sane epileptics have been divided, according to their interparoxysmal condition, roughly into four classes, showing slight, profound, or intermediate degrees of mental deficiency, and the general features of those classes may be briefly described as follows.

Class A.—In this division are included all those epileptic individuals in whom no mental impairment can be detected. They may be regarded as differing in no way from normal persons in the same social sphere and with similar educational advantages; the memory is good, they are bright, active, and intelligent, and they are capable of earning their own living; only in rare instances do they show the epileptic face. Their physical condition is good. For all practical purposes they may be regarded as normal.

Class B.—This class, to which the majority of epileptics belong, includes those who exhibit the first degree of mental enfeeblement, which is characterised mainly by some defect of memory, more especially a forgetfulness of recent events. In other respects their mental condition is good, they have fair intelligence and capacity for work, they are able to earn their living and to attend to their several duties. Their physical condition varies. A considerable proportion show the epileptic face.

In *Class C* are found those cases which present the second degree of mental impairment. In addition to an impaired memory there are defective power of initiation and capacity for work which, however, may be well done under direction and supervision. They are slow in comprehension and are often lazy. Many of them are irritable and passionate. About 50 per cent. show the epileptic face.

Class D contains those who show the third or most pronounced degree of dementia. They present the typical features of epileptic dementia—viz., a very defective memory, confusion of ideas, poor capacity for work even under direction, absence of initiative, and a slow and dull comprehension. Although not legally insane, they require supervision. Their physical condition is as a rule good, they eat heartily, and sleep well. The majority have the epileptic face.

Under these heads the mental condition in epilepsy will receive consideration, but a passing reference may be made to certain elements in the mental state which will not be specially considered later. I refer to the *epileptic temperament.*

Epileptics are usually of a sociable disposition. The majority are possessed by a religious fervour which, forming a marked feature of their disease, contrasts strongly with their actions, these being mostly perverted, passionate, or even immoral. On the whole they are self-opinionated and possess a conceit and an assurance which are out of all relation to their achievements. Their mental perspective is in consequence entirely blurred and disproportioned, giving to their views and methods an importance which cannot be legitimately claimed for them. While admitting of striking exceptions their want of initiative is characteristic. On this account, although some are good workers, most require supervision and direction. Points also to be observed in the epileptic character, no doubt the direct consequences of the malady, are lethargy and laziness, combined with an extreme pugnacity and hastiness which make them contentious and difficult to live with.

Of the more purely mental characteristics I would refer in the first place to the temporary dulling of the memory and of the finer mental faculties which is to be observed during a temporary increase in the frequency of the fits, more especially observable at the commencement of the disease. This mental clouding should not be mistaken for the beginning of epileptic dementia; it is a common mental phase of many of the patients at the time of their admission to the epileptic colony and in the majority of cases it clears up under the judicious administration of bromides or when the patient is removed from unsatisfactory domestic or other environment. Of these characteristics, I would mention, secondly, the fleeting irritability, lethargy, impairment of memory, and even delusional state which not infrequently precede for a day or two the onset of a fit or fits. This is a condition well worthy of careful recognition, as those who live with epileptics are often able to predict a seizure. This state is, however, prodromal to the attacks and is not considered as evidence of interparoxysmal mental failure.

THE STATISTICS.

The cases forming the material for this paper are those which have been under care and treatment at the Colony for Epileptics, Chalfont St. Peter. Such cases lend themselves the more readily for observations upon the mental characteristics of epilepsy, as previously to admission they have probably experienced some form of treatment and have become in the majority of instances confirmed epileptics. For various reasons particular care is taken in the selection of the cases admitted to the colony. Mere frequency or severity of the fits does not disqualify patients for admission, but the following are, if at all possible, refused: (*a*) Those who from physical causes are not sufficiently strong to undertake some kind of active work; (*b*) those who from habitual irritability of temper and awkwardness of disposition would not live in harmony with their fellows or be amenable to rules and regulations; and (*c*) those who are imbecile, demented, delusional, or liable to dangerous impulses. In this way an attempt is made to separate the sane from the insane epileptic. The cases therefore which form the subjects of the present observations are so far as possible illustrative of the mental condition characteristic of epilepsy as met with outside asylums for the insane. There are several obvious advantages in studying epileptics in such an institution as an epileptic colony. There is, first, the fact that the patients are under constant supervision and treatment; secondly, the mode of life, the diet, and the general care and hygiene are uniform; and, thirdly, the work is apportioned according to individual capabilities and tastes.

[6] Habermaas: Allgemeine Zeitschrift für Psychiatrie, vol. lviii., p. 243.

The observations have been conducted over periods varying from six months to ten years. The number of fits is recorded on specially designed charts, whilst the mental condition and the working capabilities of the patients are noted from time to time. Treatment by bromides is reduced to a minimum, only a few patients receiving more than the 30 grains of bromide of potassium prescribed at bedtime. The total number of cases upon whom observations have been made is 161; of these 102 are males and 59 are females. They include all ages from 14 to 50 years Only one patient was admitted over 50 years of age—viz, 58 In the study of the cases the statistical method has been adopted and the results are recorded in percentages. Although, as elsewhere pointed out, objections may be raised against this method it is deemed to be the best available and the results show a marked uniformity when considered from various points of view.

STATISTICAL FACTS BEARING UPON THE INTERPAROXYSMAL MENTAL CONDITION.

The several varieties and degrees of the interparoxysmal mental state in epilepsy, the relation to the various stages and types of the disease, and the bearing upon prognosis will be discussed in detail under the following headings: (1) sex; (2) hereditary predisposition to epilepsy and insanity; (3) duration of the disease from the commencement of the convulsions; (4) the age of the patient at the onset of the disease; (5) the character, type, and combination of the seizures; (6) the frequency of the seizures; and (7) the facies epileptica.

1. *Sex.*—In this and the following tables epileptics have been classified according to the degree of mental impairment already described into four subdivisions:—

TABLE I.—*Giving the Total Number of Males and Females, with their Percentage Frequency in the Four Subdivisions of Mental Failure.*

Mental class.	Males.	Females.	Total.	Total percentage.
A	9 (8·8 per cent.)	13 (22 0 per cent.)	22	13 6
B	35 (34·3 ,,)	16 (27 2 ,,)	51	31·6
C	29 (28 4 ,,)	12 (20·3 ,,)	41	25 4
D	29 (28 4 ,,)	18 (30 5 ,,)	47	29 1
Totals	102	59	161	99·7

From this it appears that the greatest number of epileptics (31·6 per cent.) were found to belong to Class B and to show only the slightest or first degree of mental impairment. But if, on the other hand, the table be so subdivided that Classes A and B, C and D be bracketed together, it will be found that 45 per cent. belong to the former and show no, or only slight, mental deficiency, while 54·5 per cent. belong to the latter and show mental deterioration in its most pronounced forms. It is therefore obvious that the cases herein tabulated give a larger proportion which exhibit mental deterioration of a marked type.

It should, however, be pointed out that the above percentages do not faithfully depict the mental state of epileptics in general, as it is obvious that those cases which seek treatment at a colony do so on account of some mental disability which prevents them earning a living under ordinary conditions. Secondly, if the table be read in vertical instead of horizontal columns, it will be seen that a larger percentage of women (22 per cent.) escape the deteriorating influence of epilepsy than men (8 8 per cent.); but that when dementia supervenes and reaches its most pronounced form a larger percentage of women (30·5 per cent.) are affected than men (28·4 per cent.). The most frequent mental condition in males is seen to be a slight impairment of the memory and a blunting of the higher mental faculties (Class B).

If these figures are compared with those given by Habermaas a close correspondence will be found to exist between them and the cases observed at the Stettin Institute, as will be apparent from Table II.:—

TABLE II.

	Stettin Institute.	Chalfont Colony.
Intellectually normal	13 per cent.	13 6 per cent.
With poor memory	20 ,,	31 6 ,,
Feeble-minded	41 ,,	25·4 ,,
Demented	22 ,,	29 1 ,,
Total cases	226	161

2. *Hereditary disposition.*—The hereditary tendencies referred to under this heading are epilepsy and insanity. On account of the difficulty in obtaining satisfactory information on these points a large number of cases have had to be eliminated owing to the absence of any note either establishing or disproving such a family disposition. Of the total of 161 cases there was no note of a heredity to either epilepsy or insanity in 73 Table III. shows the result of the investigation among the remaining 88 cases:—

TABLE III.—*Showing the Presence or Absence of a Hereditary Disposition in 88 Cases.*

		A.	B.	C.	D.	Total.
No known heredity		11	18	9	11	49
Epilepsy	Paternal	0	8	2	3	29
	Maternal	4	5	5	2	
Insanity		1	2	2	5	10
		16	33	18	21	88

The distribution and percentages are therefore the following in the several mental classes:—

In A	there are	5	cases out of	16	with hereditary	tendencies,	or	31%
,, B	,,	15	,,	33	,,	,,		45%
,, C	,,	9	,,	18	,,	,,		50%
,, D	,,	10	,,	21	,,	,,		47%

The facts, therefore, which may be deduced from Table III. are that those epileptics who show no mental impairment (Class A), or only some impairment of memory (Class B), present a lower percentage with hereditary neurotic tendencies than those cases which exhibit dementia in its more pronounced forms (Classes C and D). This fact, taken by itself, points to the deteriorating influence which a family disposition to epilepsy or insanity has upon the mental condition of those who subsequently develop epileptic seizures.

The table may profitably be compared with one which was given in a previous paper[7] to illustrate the effects of a hereditary history upon the general results of treatment in epilepsy. From this it was seen that of those cases which had a hereditary disposition to epilepsy 36 per cent. became confirmed epileptics, while of those without such history only 19·2 per cent. became confirmed.

The general deduction, therefore, which may be drawn from the above facts is that a family tendency to either epilepsy or insanity, although offering no obstacle to the arrest of the seizures in favourable cases, materially increases the probability of the disease becoming confirmed and the supervention of dementia.

3. *Duration of the disease.*—The influence of the duration of the disease upon the degree of mental decrepitude has been regarded by many writers as of much significance. In opposition to the commonly expressed opinion upon this matter Russell Reynolds held to the belief that the duration of epilepsy from the commencement of the seizures was without influence upon the mental condition of the epileptic. A table has therefore been constructed with a view to

---

[7] Transactions of the Royal Medical and Chirurgical Society, loc. supra cit.

throw further light upon this part of the subject. A total of 160 cases has been used in the construction of Table IV., which gives the duration of the disease in quinquennial periods, with the number and percentage frequency of the cases in the four classes of mental disability. It should be specially borne in mind that the term "duration" here signifies the length of the disease as indicated by the epileptic seizures and not of the mental impairment alone.

TABLE IV.—*Showing the Duration of the Disease and the Number and Percentage Frequency of the Cases in the four Mental Classes.*

Duration (years).	A.	B.	C.	D.	Total.
Under 5	6 (27·2%)	10 (45·0%)	3 (13·6%)	3 (13·6%)	22
6 to 10	13 (30·9%)	10 (23·8%)	7 (16 6%)	12 (28·5%)	42
11 ,, 15	1 (3·1%)	10 (31·2%)	10 (31·2%)	11 (34·3%)	32
16 ,, 20	1 (3·5%)	4 (14 2%)	10 (35·7%)	13 (46·4%)	28
21 ,, 30	1 (4·7%)	8 (38 0%)	4 (19·0%)	8 (38 0%)	21
Over 30	1 (6·6%)	6 (40·0%)	7 (46·6%)	1 (6·6%)	15
Mean duration... ...	3·8 years.	8 years.	6·8 years.	8 years.	160

From a consideration of Table IV. the following general deductions may be made: 1. That under five years' duration there is a considerably greater percentage of cases with no mental impairment, or merely some interference with the memory (Classes A and B, 72 per cent.), than of those with well-marked mental deficiency (Classes C and D, 27 per cent.). 2. That of those cases in which the disease has existed from six to ten years there is a slightly greater percentage in Classes A and B (54·5 per cent.) than in Classes C and D (45 per cent.). 3. But that if the convulsions have lasted for periods over 10 or 11 years only a trifling percentage of cases are to be found in Class A, the majority showing the mental characteristics of Classes C and D. 4. It should, however, be especially pointed out that in a very few cases the disease may have lasted for periods of 30 or more years without any obvious mental impairment.

It has been stated by Russell Reynolds that if the mean duration of the disease in the several classes be taken it will be found that its influence upon the mental condition is trivial. Further reference to Table IV. will show that the mean duration of the disease in Class A is 3 8 years, while that of Classes B, C, and D varies from 6·8 to 8 years. There is not, therefore, that progressive increase in mean duration in the several mental classes that might be expected, for the difference between the mean duration of Class A, which contains those cases without any obvious mental impairment, and Class D, comprising those with the greatest degree of dementia, is about four and a half years, being practically the same as that between A and B, in which latter class we find those with merely some impairment of memory. It may therefore be concluded that although the duration of epilepsy from the commencement of the seizures is a potent factor in determining the subsequent mental condition it is not the only influence in the production of dementia.

4. *Age at onset.*—There is a total of 157 cases in which the age at onset of the disease was known. In order to gauge the influence, if any, which this factor has in determining the subsequent mental condition of the patient a table has been constructed giving the number and percentage frequency of epileptics in the four mental classes, the age at onset being subdivided into quinquennial periods from birth to 35 years.

TABLE V.—*Showing the Age in Quinquennial Periods at Onset of the Fits, with the Number and Percentage Frequency in the Four Mental Classes.*

Age (years).	A.	B.	C.	D.	Total.
0 to 5	1 (3·3%)	9 (30·0%)	9 (30·0%)	11 (36·6%)	30
6 ,, 10	3 (11·5%)	8 (30·7%)	7 (26·9%)	8 (30 7%)	26
11 ,, 15	10 (18·1%)	15 (27·2%)	17 (30 9%)	13 (24·5%)	55
16 ,, 20	7 (24·1%)	8 (27 6%)	5 (17·2%)	9 (31·0%)	29
21 ,, 25	0	4 (57·1%)	1 (14 2%)	2 (28·5%)	7*
26 ,, 30	1 (16·6%)	1 (16·6%)	1 (16·6%)	3 (60·0%)	6*
31 ,, 35	0	2 (50·0%)	0	2 (50·0%)	4*
					157

* The small number of cases shown here is due to the fact that at the epileptic colony epileptics are preferably admitted under 20 or 21 years of age.

From Table V. we may deduce the following general conclusions: 1. That a low percentage of the cases forming Class A is to be found amongst those epileptics in whom the disease commences in early childhood; amongst them also is to be found a high percentage of those showing profound mental impairment and if we exclude those in whom the disease commenced after 21 years of age owing to the smallness of the numbers the lowest percentage of cases with mental integrity and the highest with mental infirmity are to be found amongst those epileptics in whom the disease commences in infancy and early childhood. 2. From the first quinquennial period onwards to that of 16 to 20 years of age the percentage of cases showing no obvious mental deficiency progressively increases until in the fourth quinquennium (from 16 to 20 years) a greater percentage of cases is to be found in the combined Classes A and B (51·7 per cent) than in the combined Classes C and D (48·2 per cent.). 3. No general deductions may be safely drawn from the cases in the succeeding quinquennial periods owing to the fewness of the cases observed, but it may be said in general terms that in epilepsy commencing over 21 years about an equal percentage show only impairment of memory (Class B) and the higher degrees of mental deficiency (Classes C and D).

These results are at variance with what was noticed by Russell Reynolds working along similar lines. This observer noted that whether the disease commenced early or late in life more cases were to be found in Classes A and B than in C and D—in other words, "that the mind is not specially affected in those whose epilepsy begins early, neither is it in those whose disease is late in its development" (p. 166, op. cit.). On the other hand, the results obtained in this present research support the contention of most of the older writers on epilepsy and confirm what has been pointed out in a previous article upon general prognosis (loc. cit., p. 268)—viz., that epilepsy commencing in infancy and childhood is least favourable for arrest of the fits and most favourable for the production of confirmed cases. It is also found that the common type of epilepsy—that commencing during the period of puberty—is most suitable for arrest of the seizures and least likely to be associated with mental infirmity.

5 *Character of the fits.*—The character of the epileptic seizures has for long been regarded as an important factor in determining the mental condition. It is generally accepted that the petit mal variety exerts a greater deteriorating influence upon the mind than the convulsive or grand mal type. This is no doubt the common experience of those through whose hands numbers of epileptics pass. A table has therefore been constructed to show the effect of the two common types of seizure upon the mental state. A total of 159 cases has been used in whom the character of the fits was definitely known.

TABLE VI.—*Showing the Percentage Frequency of the Four Mental Classes in the Common Types of Epilepsy.*

Type.	A. Per cent.	B. Per cent.	C. Per cent.	D. Per cent.	Total.
Grand mal only	24·3 ...	27·0 ...	27·0 ...	21·6 ...	74
Petit mal only	7·1 ...	42 8 ...	21·4 ...	28·5 ...	14
Combined grand and petit mal	4·2 ...	32·8 ...	25·3 ...	38·9 ...	71
					159

The grand mal type, therefore, when occurring alone is not found to be characteristically accompanied by profound mental impairment, for the table shows an almost equal percentage of cases in the several mental classes. On the other hand, the greatest frequency and highest degree of dementia are to be found in those cases which are characterised by a combination of the grand and petit mal attacks, only 4 per cent. of such cases being found without any obvious mental impairment.

The general deductions therefore are:—(1) Mental deterioration is found in association with both types of seizure, but its presence is less frequent in those cases in which the grand mal is the main expression of the disease; (2) freedom from mental impairment is also found in both types but to a minimal extent in those cases characterised by petit mal whether alone or in conjunction with grand mal; (3) the mind is more frequently affected to a slight extent (Class B) in those cases in which the petit mal seizures occur alone; (4) the mind attains its most universal and profound impairment when the disease is manifested by a combination of grand and petit mal attacks. In amplification of these statements it may be mentioned that figures have been brought forward to show (loc. cit., p. 274) that the grand mal seizures are the most readily influenced by treatment, while distinctly less favourable are the cases of combined grand and petit mal.

6. *Frequency of the seizures.*—In order to facilitate the consideration of the influence of the frequency of the epileptic attacks upon the mental condition the fits have been divided into those which may be conveniently counted by the day, the week, the month, the quarter, and the year. There have been added in a separate column those whose incidence is especially in series, while a special group has been formed of those cases in which the fits have been arrested.

In an institution such as the Colony for Epileptics it is a comparatively easy matter to register the number of the seizures and at the Chalfont Colony this is done on specially constructed charts so that at a glance there can be seen the daily, weekly, monthly, &c., incidence of the seizures, whether grand mal or petit mal in character, and whether they occur by day or during sleep. By fits occurring in series I refer to those specially interesting cases where, in place of one or two fits occurring at a time, series of fits, sometimes amounting to several score, occur over a short period, to be followed by a variable interval of freedom before the succeeding batch ensues.

TABLE VII.—*Showing the Percentage Frequency of the Attacks in the Four Mental Classes.*

Frequency.	A. Per cent.	B. Per cent.	C. Per cent.	D. Per cent.	Total.
Daily (one or more)	0·0	17·4	27·9	55·5	18
Weekly (one or two)	1·3	26·3	33·3	39·0	72
Monthly (one or two)	25·7	48·5	17·1	8·5	35
Quarterly (one or two)	57·1	14·2	28·5	0·0	7
Yearly (one or two)	50·0	50·0	0·0	0·0	8
In series	7·6	23·0	23·0	46·1	13
Arrested cases	50·0	16·6	16·6	16·6	6
					159

At the first glance there will be noticed a definite relation between the frequency of the seizures and the mental state to such an extent that when the fits are of very frequent recurrence (daily), none of the patients were without obvious mental impairment, over 50 per cent. of them being in Class D, and therefore exhibiting the highest degree of dementia. On the other hand, if the seizures are so infrequent as to be counted by the quarter or year, over 50 per cent. were found in Class A while none at all were grouped in Class D. Between these extremes there are various gradations, so that the general statement may be made that there is a direct relationship between the frequency of the seizures and the degree of mental impairment—the more frequent the attacks the more common and profound the associated dementia.

If attention is now directed to those seizures the recurrence of which is characterised by batches, it will be observed that in this type we are dealing with cases unfavourable to the maintenance of mental integrity, considerably more than double the number of such patients being found with the severer grades of mental deficiency (69·1 per cent.). In this type of epilepsy, therefore, we are confronted with a variety of the disease prone to the development of dementia

The mental state of those cases in which the seizures have been arrested, either with or without treatment, presents features of great interest, for the table shows that even when the fits are arrested there is not necessarily an unimpaired mental state remaining—that is to say, that arrest of the seizures does not *ipso facto* imply arrest of the disease. The significance of this will be considered with other points in a later paragraph.

Nothing illustrates more forcibly the severity of the disease than the frequency of the seizures, for in addition to the close association between frequency of seizures and mental deterioration there is a remarkable relation between the frequency and the arrest of the fits. Attacks which recur every three or four months or once or twice a year show the highest percentage of arrested and the lowest percentage of confirmed cases; and the converse also holds good, in that attacks recurring so often as several times a day show no cases of arrest (op. cit., p. 273) just as in Table VII. they show no cases of mental integrity.

7. *The facies epileptica.*—The close relation which exists between mental disability and facial expression is nowhere more readily seen and studied than in cases of confirmed epilepsy. So characteristic indeed is the facial appearance of many epileptics that the term "facies epileptica" has been applied to it. Although difficult to define it is readily discerned by those who are in the habit of treating large numbers of epileptics. It may, in general terms, be described as an expression of dulness and heaviness, with an absence of emotional mobility of the features. It differs from that of the ordinary dement by a particular expression which stamps the individual as an epileptic. That the epileptic appearance is largely dependent upon the mental attitude may be seen from Table VIII., which has been constructed to show the percentage frequency of the facies epileptica in the four mental classes.

TABLE VIII.—*Showing the Frequency of the Facies Epileptica in the Mental Classes.*

	A	B.	C.	D.	Total.
Total cases	22	51	41	47	161
Facies epileptica seen in	2 or 9·0%	16 or 31·3%	21 or 51·2%	34 or 72·3%	73 or 45·3%

Of a total, therefore, of 161 cases 73, or 45·3 per cent., showed the expression of countenance known as the facies epileptica. Its presence was noted in those with mental integrity as well as in those showing the several degrees of dementia but its percentage frequency showed a progressive accession as the degrees of dementia increased, until in Class D as many as 72·3 per cent. of the epileptics showed the characteristic expression. It is more frequently seen in male than in female epileptics, for of the 73 cases only 19 were women.

IS THE INTERPAROXYSMAL MENTAL CONDITION IN EPILEPSY AN INTEGRAL PART OF THE DISEASE?

It is generally known, and the observation has been amply corroborated by the foregoing statistics, that both mental integrity and mental impairment may be found amongst epileptics, but the question arises whether the mental condition which characterises the interparoxysmal period in many epileptics forms an integral feature of the disease, or is induced by the character, the duration, and the frequency of the seizures, or by any other peculiarity of the malady. As reference has already been made to the views of the earlier physicians upon this subject and the divergence of opinion which is held upon it, it is only necessary in this place to consider how far the present statistics throw any further light upon the solution of the question.

In the first place, it may be stated that mental failure is not essential to the idea of epilepsy. On the one hand, it is seen that a certain number of epileptics present no obvious mental deficiency, notwithstanding an inherited predisposition to the disease, a duration of the malady for from 20 to 30 years, its onset in early life, the combination of both the major and the minor seizures, and a recurrence of the seizures so frequent that they may be counted by the week. On the other hand, it has been shown that pronounced dementia may exist when there is no known heredity, when the disease is of short duration (under five years), when the age at onset is as late as the fourth decennium, whether the attacks are of the grand or petit mal type, and even when the seizures have been completely arrested.

Secondly, an attempt will be made to show on the basis of the collected cases that the mental condition is not a direct consequence of the seizures, but is an expression of the same nervous constitution which gives rise to the convulsions, but influenced by various coexistent factors, such as hereditary disposition, duration of the disease, age of the person at the onset of the convulsions, and the character and frequency of the paroxysms.

(*a*) A hereditary disposition to epilepsy and insanity—in other words, a family degenerative neurosis—favours the production of the severer types of dementia and the establishment of the disease as a confirmed malady, as shown in Table III.

(*b*) The duration of the disease is a potent factor in determining the mental condition, but its influence is incidental to, rather than causative of, the mental decrepitude, for, as is shown in Table IV., a fair percentage of cases of extreme dementia are met when the disease has lasted less than five years, as well as a percentage of cases with mental integrity after the fits have persisted for over 50 years.

(*c*) Upon the character or type of the seizures depends to a large extent the degree of mental impairment. But dementia and mental integrity are inversely associated with the severity of the attacks, the major convulsions being as commonly accompanied by mental health as by profound dementia. On the other hand, the minor seizures are more frequently found with mental failure than with mental health (Table VI.). The nature and combination of the attacks therefore provide an indication of the severity of the disease. The petit mal attacks when occurring alone are more frequent than the grand mal under similar conditions, but the combination of the two kinds occasions a frequency and intensity of the seizures, which furnish an indication of the degree and intensity of the malady. But the character of the seizures, though influential, is not solely responsible for the mental condition, for it is found that both types, separately or in combination, are associated with mental integrity as well as with mental deficiency.

(*d*) The facies epileptica is found in those who show the slighter as well as the more profound degrees of dementia, but there is also a very small percentage of epileptics with normal mental attitude in whom this feature is present. Although its presence is not directly referable either to the degree of mental. infirmity or even to any mental deficiency at all, the proportion of cases in which it is observed is in direct relation to the intensity and severity of the mental decrepitude. Hence the facies epileptica is another feature of the degenerative neurosis producing the disease, of which convulsions and mental impairment are further symptoms. The severity of the disease, therefore, is gauged by the combination of the grand and petit mal attacks, by the degree of dementia, and by the occurrence of the facies epileptica.

(*e*) There is a direct association between the frequency of the seizures and the mental state, for the more frequent the attacks the greater the degree of mental impairment and *vice versâ*. If the severity of the disease in any given case is gauged partly by the frequency and partly by the character-combination of the paroxysms then it is found that the severer the disease the greater the tendency towards dementia. For it is a well-recognised clinical fact that attacks which recur daily or weekly are rarely either of the major or minor types alone, but a combination of the two, with the minor variety the more obtrusive. And in this relation attention may be also directed to that class of epileptic in whom the fits are especially in series. These cases indicate a modification of the disease, with periodic exacerbations of extraordinary intensity and in them we find a high percentage of dements. We have also seen that there exist certain cases of epilepsy where the fits have been arrested either spontaneously or by treatment. In these all classes of mental impairment may be met, so that arrest of the seizures does not necessarily imply arrest of the disease.

(*f*) The age at which the disease commences, which is determined by the onset of the seizures, influences to some extent the subsequent mental condition; in other words, the earlier the onset of the fits the less the probability of an unimpaired mental condition and the greater the chance of the establishment of confirmed epilepsy. The type of cases found in institutions for epileptics shows this more obviously than those which remain outside, no doubt on account of the greater severity of the disease in the former, indicated by the greater frequency of the seizures and by the combination of the major and minor types.

The evidence adduced in this paper tends to support the view that the earlier the onset of the disease, especially under ten years of age, the greater the probability of mental failure, but that the small percentage of cases admitted to the colony over 25 years of age does not permit of any definite statement being made as to what occurs when the disease is late in onset.

SUMMARY AND CONCLUSIONS.

1. A total of 161 cases, which have been under my observation at the Colony for Epileptics, Chalfont St. Peter, has been used for the investigation.

2. The mental features of the interparoxysmal state have been divided for descriptive purposes into four classes, the first containing those epileptics without any obvious mental impairment and the fourth those with the highest grade of dementia.

3. The interparoxysmal mental condition is discussed in its several varieties and degrees, with special reference to the influence of sex, hereditary disposition, age at onset, and character, duration, and frequency of fits.

4. Sex has little influence upon the mental condition, but it may be stated in general terms that males are numerically more afflicted than females (91 per cent. of the former to 78 per cent. of the latter) but that the highest degree of dementia is somewhat more common in women than in men.

5. A family predisposition to epilepsy and insanity, although not necessarily militating against the retention of normal mental faculties, favours the supervention of some degree of mental impairment. A higher percentage with a hereditary history is found amongst those epileptics who show the profounder degrees of dementia, than amongst those who show merely impairment of memory or a normal mental condition.

6. The duration of the disease influences to some extent the mental condition. Mental impairment is less frequent when the fits have lasted for under five years, just as mental integrity is less commonly seen when attacks have persisted for ten or more years. But mental health and mental deficiency are observed in cases in which the disease has lasted respectively for over 20 years and for less than five years.

7. The age at the onset of the convulsions influences to some extent the subsequent mental condition, for the earlier the onset, especially during infancy and childhood, the less the probability of an unimpaired mental state.

8. The character and combination of the fits have an important relation to the mental condition, the profoundest degrees of dementia being most commonly seen when the major and minor attacks coexist. The petit mal seizures occurring alone are found with the lower grades of mental impairment. When the grand mal occurs alone mental health is as common as mental deficiency.

9. There is a direct association between the frequency of the fits and the mental state—the more frequent the seizures the greater the degree of mental impairment and *vice versâ* Fits recurring in series are accompanied by a high grade of dementia.

10. The term "facies epileptica" is applied to the physiognomy characteristic of the disease in many epileptics. It is found more commonly with the higher grades of dementia but its existence is not limited to such cases, for it is observed in those with only impairment of memory as well as without any mental failure.

11. The view is upheld that the interparoxymal mental condition seen in most cases of epilepsy is one expression of the neurosis of which the fits constitute another; that the former is therefore not directly dependent upon the seizures and that the frequency and character-combination of the paroxysms in association with the degree of mental failure indicate the severity and intensity of the disease.

12. The following figures show the percentage frequency of the four classes of mental deficiency amongst the 161 cases used for the purposes of this paper: Class A, intellectually normal, 13 6 per cent.; Class B, with impaired memory, 31·6 per cent.; Class C, feeble-minded, 25·4 per cent.; and Class D, demented, 29 ·1 per cent.

Harley-street, W.

THE CARDIAC DULNESS IN CASES OF CANCER.[1]

BY W. GORDON, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL.

I WOULD venture in as few words as possible to draw attention to a physical sign which has, I think, hitherto escaped notice, yet one which, if my observations prove correct, should be found valuable in a considerable number of cases.

Some years ago in the routine examination of several patients with gastric cancer I observed that although no evidence existed of ordinary emphysema the area of cardiac dulness, mapped out in the recumbent position, was either much reduced or actually obliterated. In some of them where the dulness was obliterated the resonant note over the heart was, it is true, slightly higher pitched than over the lung but it was definitely resonant, not dull. The reduction or obliteration of the cardiac dulness was sometimes associated with a rather surprisingly small and soft pulse.

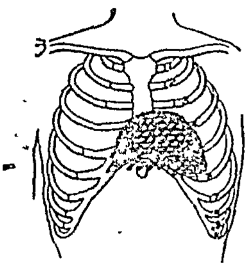
Since my first observations I have often noticed this curious physical sign and some time ago I became so sure that it suggested cancer that I risked the diagnosis of cancer on the strength of it where otherwise the evidence was inconclusive and in five consecutive cases the diagnosis proved correct.

---

[1] A paper read before the Royal Medical and Chirurgical Society on March 8th, 1904.

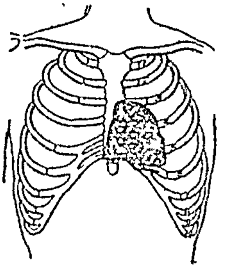
The reduction or obliteration of the dulness was observed, as I have said, in the recumbent position. It is necessary to insist on this point because our text-books do not clearly recognise the differences in the physical signs of the heart which exist in the recumbent and upright positions. As the result of many observations on healthy and diseased hearts I have found that the heart dulness alters considerably with change of position. Figs. 1 and 2 illustrate the change in the cardiac dulness which usually occurs when a healthy adult changes his position from the upright to the recumbent. Fig. 3 illustrates the reduction in the recumbent dulness in a case of cancer [illegible] ated. The following ca [illegible] this physical sign, be [illegible] ancer was arrived at pc [illegible]

FIG. 1.



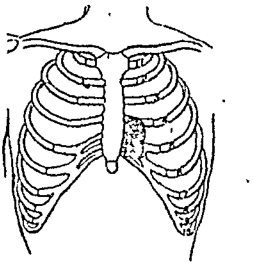
Normal cardiac dulness in the upright position.

FIG 2.



Normal cardiac dulness in the recumbent position.

FIG. 3.



Cardiac dulness in a case of cancer where it has not been yet obliterated.

CASE 1. *Pain; vomiting; moderate loss of weight; no tumour; loss of cardiac dulness; operation; gastric cancer.*—A man, aged 42 years, a labourer, complained of epigastric pain relieved by food. This had come on six months previously but disappeared under treatment. It reappeared two and a half months before his admission to hospital, accompanied by flatulence and headache. Three weeks before his admission he began to be sick, but more after fatigue than after food. Once only he noticed a very little blood after much retching. He was not at all wasted in appearance but said that he had lost flesh. There was almost no cardiac dulness, although there was no indication of ordinary emphysema. His chest was of normal shape and expanded well on inspiration. There had been no winter cough and there had been no breathlessness. Examination of the stomach contents after a test meal showed absence of free hydrochloric acid and presence of lactic acid. No tumour could be felt. I advised laparotomy, hoping that early operation might reveal a cancer which could be removed. My colleague Mr. J. D. Harris found a cancer of the anterior wall of the stomach but considered that its extent and attachments rendered extirpation impossible.

CASE 2. *Profuse hæmatemesis; loss of cardiac dulness; rapid wasting and development of a tumour.*—An elderly woman, after some weeks of indefinite gastric symptoms, was seized with a profuse hæmatemesis. She was stout and her appearance gave no suggestion of malignant disease. There was no evidence of emphysema, but her cardiac dulness was absent. The bleeding having been arrested feeding by the [illegible] ossible, but she wasted [illegible] llock, with whom I had [illegible] a well-marked tumour could easily be made out in the region of the stomach. A necropsy could not be obtained.

CASE 3. *Wasting; tumour; loss of cardiac dulness; death; necropsy; gastric cancer.*—A woman, aged about 45 years, was seen by me with Mr. J. Miller. She had been losing flesh and a tumour had developed to the left of the umbilicus and a little below it. She had obviously no emphysema but her cardiac dulness had disappeared. I decided that the tumour was a pyloric cancer and this diagnosis was found correct by Mr. Miller who performed a necropsy.

CASE 4. *Dysphagia; absence of cardiac dulness; subsequent paralysis of the right vocal cord; death; necropsy; cancer of the œsophagus.*—A man, aged about 45 years, was seen by me with Mr. B. Dyball. He was then complaining of difficulty of swallowing which had been coming on gradually. He was a well-nourished but highly nervous man. As aneurysm seemed exceedingly improbable in his case I passed a No. 21 bulbous œsophageal bougie. This was gripped once or twice but the grip relaxing before gentle steady pressure the bougie passed fairly easily into the stomach. It appeared uncertain whether the case was one of cancer or spasm. He had no emphysema, the chest expanding well, but the heart dulness had entirely disappeared. The pulse, too, for a man of his appearance, was surprisingly small and soft. I suspected cancer but deferred a definite opinion until I had seen him again. A couple of weeks later Mr. Miller, who was looking after him in Mr. Dyball's absence, asked me to see him. His voice had become hoarse. I found paralysis of the right vocal cord. The diagnosis of cancer was then definitely made. On the patient's death Mr. Miller made a careful post-mortem examination and found two broad cancerous areas in the œsophagus. The heart was of normal size but the lungs completely overlapped it.

CASE 5. *Dysphagia; loss of cardiac dulness; death; necropsy; cancer of the œsophagus.*—A man, aged 35 years, came to hospital complaining of difficulty of swallowing. There was no emphysema but the cardiac area of dulness [illegible] breadth at the level of the fourth [illegible] e was extremely small and soft. [illegible] opening into the trachea was discovered post mortem.

CASE 6. *Intestinal obstruction; loss of cardiac dulness; operation; cancer of the descending colon.*—An elderly woman was seen by me for the first time on the operating table. She had intestinal obstruction and there was a question as to whether this was caused by a cancer of the descending colon. Owing to the abdominal distension it was impossible to arrive at any conclusion by palpation. There was absolute loss of cardiac dulness and I ventured to predict that a cancer would be found. In the course of the colotomy an extensive cancer was discovered in the colon above the sigmoid flexure.

These six cases illustrate sufficiently the usefulness of this physical sign as an aid to diagnosis in certain cancerous cases. My experience with regard to it lies chiefly amongst cases in which some part of the alimentary canal is involved. Whether it is equally frequent in cases of cancer of other parts, such as the breast, I am unable to say. I have seen it in breast cases but I have also found it wanting in these when I should have expected it to be present. Its diagnostic value in cases where it occurs depends, of course, on its absence in other conditions. I have looked for it carefully in a very large number of non-cancerous cases, with or without wasting, and with or without a resemblance to cancer as regards symptoms. So far as my experience goes it is very uncommon to find the heart dulness lost or markedly reduced in area in non-cancerous cases where emphysema can be excluded, but heart dulness is not invariably present in non cancerous cases any more than it is invariably absent in cancerous cases. All one can claim for the sign is that when present in a doubtful case it is highly suggestive of the presence of cancer and when absent at a late point in the case its absence is somewhat suggestive of the absence of cancer.

With regard to the period of the loss of cardiac dulness in a cancerous case one may say that it may precede cachexia, pronounced wasting, or the loss of skin elasticity which is often obvious, especially in the abdominal skin, in abdominal cancer cases. Unhappily, it does not seem to be usually so early a symptom as to make a practical difference in the date of attempts at extirpation of the disease. Although it has, perhaps, enabled me more than once to suggest an exploratory operation earlier than I should otherwise have done I have as yet only met with one case in which *absence of cardiac dulness* has helped on a successful removal of the growth.

In assessing the value of absence of heart dulness in any given case one would, of course, take into account not merely emphysema but any cause capable of withdrawing the heart from contact with the chest wall, such as the retraction of adhesions in the back of the pleural cavity. Conversely, in assessing the value of a normal heart dulness where cancer is suspected, one would naturally consider causes which might prevent the dulness being decreased, such as enlargement of the heart from any cause, pericardial effusion, retraction of diseased lungs, adhesions to the front of the chest, or pressure from behind pushing the heart forwards. The following three cases illustrate the presence of a normal heart dulness in non-cancerous cases where cancer has been suspected.

CASE 7. *Chronic jaundice; wasting; pain; cardiac dulness normal; operation; no cancer; recovery.*—A woman, aged 49 years, had had pronounced jaundice for nine months, occasional severe pain in the right hypochondrium, especially after food, occasional vomiting, and considerable loss of weight. In 12 months she had come down from 11 stones 8 pounds to 9 stones 12 pounds. The liver was uniformly enlarged. There was no ascites. The motions were persistently clay-coloured. The appetite varied. Under medicinal treatment the pain and sickness lessened, the jaundice slightly decreased, and she gained weight slowly. Three months later I was sent for to see her by her medical attendant, Mr. H. E. Goulden. She had had a very severe attack of pain and vomiting. She had become thin again. The heart dulness was rather larger than normal, although cardiac and renal disease were absent. I advised operation with a view to the removal of a possible gall-stone in the common bile-duct. The possibility of cancer was discussed and I decided against it. Mr. Russell Coombe operated and found no cancer. No gall-stone was discovered, but as a result of the manipulation of the bile-duct some obstruction was evidently removed as the patient has made a complete recovery, her jaundice having disappeared.

CASE 8. *Jaundice; wasting; normal heart dulness; recovery.*—An elderly woman, very thin and sallow, almost cachectic-looking, with pronounced jaundice and a history of loss of weight, was seen by me with Mr. Miller. Her history was most difficult to elicit and the duration of the jaundice was doubtful. The liver was enlarged and tender. The cardiac dulness was of ordinary size, and no cardiac or renal disease existed. The case strongly suggested cancer, so strongly that I did not feel justified in deciding definitely against it, but on the strength of the broad heart dulness I gave more hope of recovery than I could otherwise have done. Under treatment the jaundice disappeared, the patient gained flesh, and recovery now appears to be complete.

CASE 9. *Abdominal tumour; cardiac dulness normal; operation; "caseous kidney."*—This patient, a man in middle life, was seen by me after the exploratory operation. The broad cardiac dulness would have, I think, decided me against carcinoma.

It would, no doubt, be rather rash to lay great stress on the absence of reduction of the cardiac dulness but, as a matter of experience, its absence seems to me to have, as in these three cases, a certain value of its own. The following case, however, shows that a normal cardiac dulness may persist even to the end of a case of gastric cancer, though its persistence in such a case is, I think, very uncommon. Usually, when the heart dulness is normal in the early stages it becomes greatly reduced or obliterated towards the end. The absence of reduction of the cardiac dulness in this case is particularly interesting, as the growth was exceptionally circumscribed and chronic in character.

CASE 10. *Pyloric obstruction; great wasting; normal cardiac dulness; death; necropsy; small hard cancer.*—A man, aged 46 years, had been vomiting profusely on and off for about nine months. Six months before I saw him a diagnosis of non-malignant pyloric obstruction had been made in America and he had been taught to wash out his stomach daily. In view of an old history of severe pain near the pylorus it was possible that the obstruction might be due to the cicatrisation of an ulcer. He was extremely thin but I could discover no tumour. The cardiac dulness was normal. I advised such treatment as seemed necessary to stop the sickness and to promote gain in weight and directed that as soon as his condition was somewhat improved operation should be undertaken, either gastro-enterostomy or, if a cancer existed and seemed removable, pylorectomy. His sickness ceased and in five weeks he put on nearly a stone in weight. Unfortunately the latter half of my advice was not carried out and he came under my care again when his old symptoms had returned and when his condition made operation impossible. At the necropsy the pylorus was found stenosed and indurated but not enlarged in its outside dimensions. A slowly growing, very circumscribed cancer spread from it a short way into the gastric wall. Only one or two neighbouring glands seemed affected. The growth evidently was one of slight general and local malignancy, the patient having died chiefly from its mechanical effects.

The following case was one in which the cardiac dulness, normal when first examined, slowly decreased in size under observation.

CASE 11. *Pain; wasting; cancer of the stomach at the œsophageal orifice; gastrostomy; cardiac dulness slowly decreased.*—The patient came under my care in hospital. My colleague, Mr. A. C. Roper, performed gastrostomy and found a large cancer growing into the stomach at the œsophageal orifice. The heart dulness was then normal. During the patient's quiet life in hospital after the operation I noticed that the area became slowly but steadily smaller.

In non-cancerous cases I have seen the cardiac dulness markedly reduced in three instances only. I do not think I have ever seen it lost. One case was a woman with a large uterine fibroma. She was seen two years ago and is now well. The second was a case of chronic diarrhœa which I had only a short time under observation and believe to have been tuberculous. The third was a man with chronic gastritis who is much better at present, 18 months having elapsed since I saw him.

The cause of this curious physical sign has, of course, been a matter of interest to me. At first I fancied that the reduced area of dulness might be accounted for by the reduced size of the heart, because the heart is supposed to waste disproportionately quickly in cancerous patients. But a few post-mortem examinations made this theory untenable. The heart was not strikingly small—one heart was rather over the average in size, I should say—but in each case the lungs met, or nearly met, over it. The encroachment of resonance on the heart dulness was thus easily explained. But it is less easy to explain this forward movement of the lung edges. Perhaps that may be best accounted for by supposing that, just as in many cases of cancer, of abdominal organs especially, the skin of the abdomen becomes strikingly inelastic, so a similar loss of elasticity may occur in the lung structure, whereby even ordinary breathing can cause a sort of false emphysema in consequence of which the edges of the lungs gradually close over the front of the heart. If this be the true explanation it will account for the fact that in the earliest stages of cancer the sign is not present and for the further fact that in sarcoma, which does not affect skin elasticity as cancer does, I have so far failed to find it.

In conclusion, I would sum up thus the result of my observations. Putting aside cases where special causes exist, either for the obliteration of the heart dulness or for the prevention of such obliteration, the following seem to be true: 1. Great reduction or obliteration of the normal cardiac dulness is common in cases of cancer, particularly in cancers of the alimentary canal and in their late stages. 2 This loss of cardiac dulness does not seem to be found in the earliest stages of a cancerous case but may precede cachexia, marked wasting, and loss of skin elasticity. 3. It is rarely observed in non-cancerous cases. 4. It is rarely absent in the later stages of cases of cancer of the alimentary canal. 5. It does not seem to occur in cases of sarcoma. 6 In doubtful cases its presence is highly suggestive of cancer; its absence is slightly suggestive of the absence of cancer, if the symptoms under consideration have lasted for several months. I should like to express my indebtedness to my friend Mr. Muller for the great help he has given me in watching cases to their conclusion and for the careful necropsies he has made to confirm our diagnoses.

Exeter.

A CASE OF REMOVAL OF A POLYPOID GROWTH FROM THE BASE OF THE SKULL AFTER A PRELIMINARY EXCISION OF THE UPPER JAW.

BY F. A. SOUTHAM, M.A., M.B. OXON., F.R C S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL SURGERY, THE OWENS COLLEGE, MANCHESTER.

THE removal of a polypoid growth when springing from the base of the skull and involving the pharynx more than the nasal fossæ is often a matter of considerable difficulty, as is proved by the fact that various methods of operation, some of which are associated with the names of Nélaton, Rouge, and Langenbeck, have been devised for this purpose. When the growth is of dense consistence and sessile, with an extensive attachment to the bone, a preliminary excision of the upper jaw affords the best access to it and also the most effectual means of controlling hæmorrhage, which is often very free during the process of [illegible] are well illustrated by the following case.

The patient, a young man, aged 22 years, came under my care in June, 1903, suffering from a naso-pharyngeal poly- [illegible] he care of Dr. [illegible] d upon him in [illegible] on each occa- [illegible] the mouth a [illegible] it had twice [illegible] patient in con- [illegible] to my care, as he was of opinion that a more radical operation was now necessary in order to insure its complete removal. When the patient came under my observation there was complete obstruction to nasal respiration. The growth could not be seen from the anterior nares, but it was apparent from the mouth, depressing the soft palate and projecting below it in the form of a globular tumour with a smooth surface. On palpation it was found to be lobulated and of very firm consistence, connected with the base of the skull by a broad attachment and completely filling the upper part of the pharynx as well as involving both nasal fossæ. In addition to the discomfort from the nasal obstruction, the patient was beginning to suffer from severe headache and great mental depression; it had been noticed of late that both eyeballs were becoming somewhat prominent, otherwise there was no external disfigurement.

On June 23rd the growth was removed in the following way, Mr. A. H. Burgess and Dr. W. H. Richardson of Preston, the patient's medical attendant, assisting me, the anæsthetic being administered by Mr. A. Wilson. The soft palate was first divided in the middle line in the hope that this procedure would allow of the application of an écraseur round the base of the tumour. This being found impracticable owing to its broad attachment, it was resolved partially to resect the left superior maxilla, to turn it outwards with the overlying soft tissues, and then having removed the growth, if this was practicable, to replace the jaw. The usual skin incision was made, commencing above at the inner angle of the eye and carried round the nose and through the centre of the lip. The left half of the soft [illegible] bony connexions [illegible] ised and turned [illegible] was insufficient room to gain free access to the base of the tumour the entire jaw was excised with the exception of the orbital plate. By this means the attachments of the tumour were freely exposed and its removal was then effected by means of a gouge, the growth being forcibly stripped off the base of the skull. In doing so the sphenoidal sinuses were opened. The detachment of the tumour was attended by very free hæmorrhage which was arrested by sponge pressure and by plugging firmly with strips of gauze. The two halves of the soft palate were then sutured together and the skin incision was closed. As regards the after-progress of the case, both wounds readily healed and the patient rapidly recovered from the operation, being able to leave the home where it had been performed on the seventeenth day.

At the present time, nine months after its performance, the patient enjoys excellent health and is free from any evidence of a recurrence of the growth. The scar on the face is hardly perceptible and the cavity left by the removal of the jaw has greatly contracted and filled in with a deposit of fibrous tissue. The opening on the roof of the mouth is closed by a plate, to which a set of artificial teeth are attached, so that articulation and mastication are in no way interfered with.

A microscopic examination of the growth showed a fibrous structure but extremely cellular in places, the appearance suggesting that it might soon become sarcomatous.

Manchester.

A CASE OF CARCINOMA PROBABLY ORIGINATING IN RETAINED TESTIS.

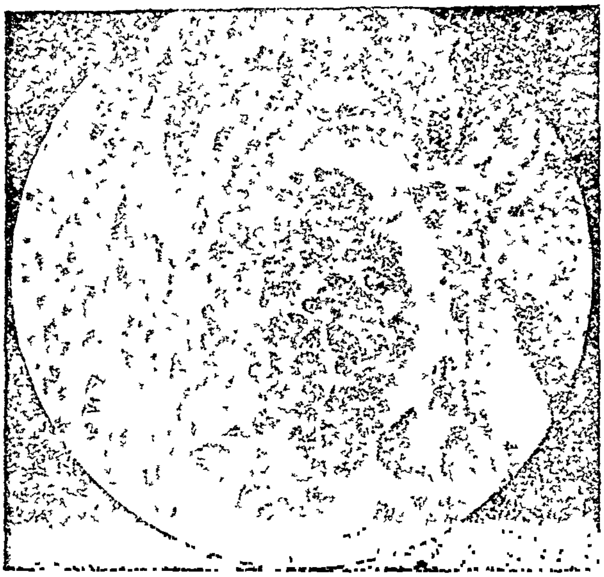
BY W. SYDNEY DARBY, M.A., M.B., B.C. CANTAB., L R C.P. LOND., M.R.C.S. ENG.

THE patient at the time of his death early this year was 24 years of age. He had a congenital left inguinal hernia and the testis was undescended on that side and could not be palpated. The penis was hypospadic. He had a rupture of one of the adductors in the right thigh, due to an accident some years previously. His body was of a slight but athletic build and his mental capacity was fully up to the normal standard. His general health previously to the onset of his disease had been excellent. He first became ill about the middle of 1902, complaining of a general weakness, pain in the back of the thighs, and œdema of the right leg (this œdema subsequently disappeared), and he went to the seaside in July of that year for the benefit of his health. There it was discovered that he had a tumour in the abdomen When I first saw him in the autumn of that year the tumour was of about the size of a large cocoanut. It was hard and smooth, firmly fixed to the lumbar spine, and slightly larger on the right side. The pelvis was free. There was marked enlargement of the superficial abdominal veins. From that time onwards the tumour gradually increased in size, more rapidly in the earlier months than in the later. From being smooth it became largely irregular and was always extremely hard and firmly fixed. As it grew it involved the lumbar plexus on the right side, causing intense pain in the right lower limb and subsequently loss of knee-jerk. About a month before death the left knee-jerk was beginning to be exaggerated. Never at any time was there any sign of the kidneys being involved or of pressure on the ureters. The diaphragm was pushed up only very slightly and did not interfere with respiration. No secondary growths could be discovered during life. Several distinguished surgeons in London saw the patient and the diagnosis to the end was retroperitoneal sarcoma, probably of the retained testis.

A full post-mortem examination was unfortunately out of the question, but I was allowed to open the abdomen and to cut a piece off the tumour. This was done at the patient's house without any facilities for the work, so that a more extensive examination could not be made. The tumour was of a pearly-white colour, occupying the greater part of the abdominal cavity and adherent by a broad base to the lumbar spine. There were no secondary growths in the liver.

I sent the specimen to the Clinical Research Association in London where some excellent sections were prepared. Mr. J. H. Targett in explaining the sections said: "The [illegible] structure is that of [illegible] of polyhedral cells [illegible] calcareous particles [illegible] This type of growth most commonly arises in the hilum of the ovary and may burrow beneath the peritoneum." Later, with fuller details of the case, he said: "It seems not improbable that the disease originated there [i.e., in the undescended testis] and that the abdominal tumour was chiefly due to secondary growths in the lumbar glands. On examining the sections again I am still disposed to call it a soft carcinoma in spite of the youth of the patient and I think the sections are from a secondary growth in the lumbar lymphatic glands. There is certainly lymphoid tissue in the stroma of the growth and it cannot therefore be a primary growth in glands. Carcinoma of the testis does occur in young subjects but I have never met with these calcareous granules in any tumour of the testis previously examined."

Sir George Brown, C.B., was good enough to take some photographs of the sections for me. The different degrees of enlargement show very clearly the structure of the growth and the character of the cells. He also made some lantern slides from the negatives which showed everything even more clearly. The calcareous particles mentioned by Mr. Targett, which I do not see in the photograph, were very clear in the greater enlargement with the lantern A large number of them had a circle of light round them as if they were encapsuled in some substance.



Harrow.

DILATATION OF THE HEART.[1]

BY E. H. COLBECK, M.D. CANTAB., M.R C.P. LOND,

PHYSICIAN TO OUT-PATIENTS AT THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK, E., PHYSICIAN TO THE METROPOLITAN DISPENSARY, FORE STREET, E C.

AMONG the many and varied problems presented to us by cardio-vascular disease there is none that compares in general interest and practical importance with the elucidation of the precise conditions which determine the occurrence of dilatation of the heart. No doubt the vital and mechanical principles which underlie the production of cardiac dilatation are in a general way more or less well understood, but the exact mode of operation of the determinant forces is still a matter of speculation. In its purely mechanical aspect the question presents little or no difficulty. The complexity of the problem arises mainly from the fact that with our present knowledge we are unable to gauge with anything like accuracy the influence both in kind and amount that is exerted by the neuro muscular factor concerned in the production of dilatation of the heart.

In this paper an attempt will be made to show that all forms of cardiac dilatation have fundamentally a common mode of origin, inasmuch as it will be contended that they all depend primarily on an absolute or relative diminution or loss of the muscular tone of the organ. Furthermore, whatever may be the merits of this hypothesis I have little doubt that I shall be able to demonstrate that its application in the pathogenesis of many forms of dilatation of the heart adds materially to the simplification of the problem of causation.

The exposition of the thesis advanced in this paper does not call for a detailed consideration of the conditions under which dilatation of the heart is observed. These conditions are well known and the factors concerned in their production will be referred to as occasion demands in the course of the development of the argument.

Dilatation of the heart is usually considered to be of two kinds according as it arises in connexion with certain forms of valvular disease or is observed in association with absolute or relative functional inefficiency of the cardiac muscle, and it will be convenient for the purposes of the present discussion to adopt this division of the subject. The intelligible presentation of the hypothesis with which we are concerned in its application to these two forms of dilatation will be greatly facilitated by a few preliminary observations on cardiac physics.

It has been shown experimentally that under normal conditions the output of blood from the left ventricle into the aorta at each systole is remarkably constant in quantity, and since this result is obtained in the face of varying aortic pressures it follows that the heart is capable of increasing or decreasing the amount of work it performs in accordance with the requirements of the circulation. Manometric measurements have demonstrated that when operating against a high aortic pressure both the maximal and average intra-ventricular pressures are higher than when the ventricle is contracting against a low aortic pressure; in other words, the heart copes with heightened blood pressure by an increased display of energy. The work of the heart is largely determined by the degree of diastolic distension of the ventricle which, speaking generally, varies with the amount of blood that remains in the ventricular cavity after the completion of the systole Roy and Adami have shown that the ventricle does not empty itself completely at each systole, so that at the end of its contraction the chamber contains a measure of blood which varies considerably in amount under different conditions. Provided the ventricular output remains unaltered the operation of diastolic distension is to increase the quantity of residual blood in the ventricle at the end of systole for the following reasons, which I quote from Sherrington's account of the subject in Allbutt's "System of Medicine." "The pressure on a unit of surface remaining the same the total intra-ventricular pressure will vary approximately as the square of the radius of the cavity if the cavity be taken as approximately spherical. Thus Roy and Adami have pointed out that distension of the ventricle means not only increase of the tension of the muscular fibres but also increase of the lateral pressure on their surface in proportion as the square of their increase in length. But as they further pointed out the content of the cavity increases as the cube, and the muscle fibres, in order to expel the same constant quantity of blood from the dilated as from the undilated ventricle, need to shorten to a relatively less extent than was required of them before. The effect of diastolic distension is, therefore, if the output from the ventricle at each systole remain the same to leave a larger residuum of blood in the ventricle at the end of systole."

Now distension of the ventricle means the stretching of its muscular walls which in accordance with the general physiological law that governs all contractile tissues is within certain limits a stimulus to increased functional activity. The display of increased functional activity is shown by the performance of a greater amount of work (lift × load) and does not necessarily imply any additional shortening of the muscle. In point of fact the amount of shortening is usually less when a muscle is considerably stretched than when it is only slightly extended. At the same time it must be borne in mind that so far as the reduction in size of the chamber by a given volume is concerned the largely distended ventricle is at an advantage as compared with the slightly distended ventricle inasmuch as, for the reasons already given, a smaller amount of shortening suffices to produce this effect in the former than in the latter case. Other things being equal the amount of blood expelled at each systole by the largely distended ventricle should be increased as compared with the normal output and experimental investigation has shown that this result is actually obtained. It does not, however, necessarily follow, as Sherrington points out, and this is the crux of the whole problem, that the wall of a largely distended ventricle is during diastole more highly loaded—that is, under greater tension—than the wall of the ventricle that is but normally distended. The tensile properties of the ventricular wall are determined and limited by the degree of its elastic reaction. Tension under the conditions with which we are concerned means the stretching of the wall of the heart against elastic resistance. The elastic resistance in the case of the ventricular wall is provided by the tonus of the cardiac muscle, which, therefore, regulates the tension of the muscle fibres and hence to a large extent the force of their contraction. It will thus appear, as Clifford Allbutt has remarked, that tension and tone bear something like an inverse relation to one another in that they are mutually provocative and antagonistic.

---

[1] A paper read before the Watford Medical Society on March 11th, 1904.

The paramount importance of the influence that is exerted by the cardiac tonus in the maintenance of diastolic distension within physiological limits and the prevention of dilatation of the heart is now readily appreciated. Thus so long as the tonus of the heart is unimpaired not only is undue diastolic distension restrained and the amount of residual blood at the end of systole restricted, but the ventricular wall is stimulated to a more vigorous contraction by the increased tension of its muscle fibres. Moreover, in these circumstances the ventricle is at a mechanical advantage, inasmuch as the smaller the cavity of the chamber the greater is the power of its contracting walls to propel their charge into the aorta, for, as Dr. Robert H. Woods has pointed out, the blood pressure inside a contracting cardiac chamber varies inversely as the radius of the chamber. On the other hand, with diminution or loss of the cardiac tonus not only is diastolic distension inadequately checked and the amount of residual blood increased but the ventricle partially or wholly lacks the stimulus to more vigorous contraction that is derived from tension of its wall (since the tension of the ventricular wall is diminished or lost), and, moreover, the chamber acts for the reason just given at a mechanical disadvantage. The wall of the ventricle consequently becomes stretched and its cavity dilated and these conditions tend to increase and to become perpetuated. Apart from the restoration and reinforcement of the cardiac tonus by hypertrophy the ventricle, even under the disadvantageous conditions just sketched, is able until its reserve power of contractile energy becomes exhausted to maintain the circulation more or less imperfectly for long periods of time. Inasmuch as tone is a later acquired and more highly specialised attribute of muscular tissue than contractility it follows from the operation of a well-recognised physiological law that the former property is more readily and profoundly affected by any interference with function than the latter. It follows, therefore, that the ventricle under the stress of long-continued overwork or under the manifold conditions which lead to interference with its nervous mechanism or nutritional integrity would lose its more highly specialised property of tone long before its primitive and inherent attribute of contractility. Herein, as I have attempted to explain, lies the initial and fundamental disability of the ventricle when from any cause it becomes unable either relatively or absolutely to carry on the work of the circulation. In this connexion I would more particularly insist on the importance of the nervous factor that is concerned in the production of cardiac dilatation by reason of the paramount influence exerted by the nervous system in the maintenance and regulation of muscular tonus. The beneficial operation of a cheerful disposition, the harmful effect of depression, the influence of joy, grief, anger, and the like, and the almost inexplicable variations that occur in the condition of the heart from day to day in cases of cardiac dilatation, are in the light of altered cardiac tonus readily explained. In order to avoid unnecessary repetition the argument has thus far been developed in relation to the question of the method of production of dilatation of the left ventricle only, but it must be clearly understood that the reasoning employed applies, *mutatis mutandis*, with equal force to the other chambers of the heart. It would therefore be beside the point to elaborate our contention with respect to these portions of the organ.

We are now in a position to examine the part played by the cardiac tonus in the production of dilatation of the heart and by so doing to test the validity of the hypothesis which forms the subject of this paper.

In the case of that form of dilatation of the heart which is observed in connexion with aortic regurgitation the explanation of the mode of operation of the cardiac tonus presents little or no difficulty. Under the conditions which obtain in aortic incompetence the left ventricle has to withstand during its diastole the distending effects of the regurgitation blood-stream under the pressure of the arterial recoil. The total intra-ventricular pressure during diastole on a unit of surface is the resultant of the respective pressures which prevail at the aortic and mitral orifices and is, of course, enormously in excess of the normal. The magnitude of the pressure that is exerted by the arterial recoil is, perhaps, more readily appreciated under experimental conditions, for it has been shown in animals that if the aortic valve be suddenly rendered incompetent the aortic pressure is sufficient to produce aneurysm or even rupture of the wall of the unprepared heart. Rupture of an aortic cusp is occasionally observed in man as the result of strain or violence and is always followed by rapid dilatation of the left ventricle.

The strain imposed on the wall of the ventricle in the conditions ordinarily connected with the incidence of aortic incompetence comes into operation gradually and its magnitude is ultimately determined by the extent of the lesion and the state of the arterial blood pressure, but in any event it constitutes the chief source of overwork which has to be performed by the heart. In any circumstances, however, it is clear that the resistance to progressive and unlimited diastolic distension of the left ventricle in aortic regurgitation must be, and is, provided by an increase of the tension of the muscle fibres of the ventricular wall, and this, as I have already insisted, is initiated and regulated by the cardiac tonus. Dilatation would quickly get the upper hand of hypertrophy at the outset were it not that the ventricle falls back on its reserve power which temporarily staves off the distending effects of the lesion. This increased display of functional activity leads under favourable nutritional conditions to hypertrophy which restores and maintains the tonus of the ventricular wall up to the level of the requirements that are demanded by the increase of intra ventricular pressure. There is, no doubt, a further cause for hypertrophy in that the ventricle has to propel a greater quantity of blood at each systole, but this factor must be comparatively unimportant compared with the task of maintaining the tonus of the cardiac wall.

The reasoning employed with respect to aortic regurgitation applies, *mutatis mutandis*, with equal force in the explanation of the mode of production of the ventricular dilatation that is observed in connexion with mitral incompetence and also with pulmonic insufficiency. The conclusion therefore with respect to that form of dilatation of the heart which arises in association with valvular disease is that it depends fundamentally on relative insufficiency of the tonus of the cardiac muscle. In other words, the ventricle dilates because the normal tonus of its muscle fibres is unable to provide sufficient elastic resistance to cope with the distensile stress of the excessive intra-ventricular pressure during diastole.

The mode of development of dilatation of a cardiac chamber from functional inefficiency of its muscular wall affords a problem the solution of which is frequently a matter of very considerable difficulty. The production of this form of dilatation of the heart depends most commonly on the coöperation in varying degrees of two main factors either of which may, however, occasionally act alone. They are: (1) an increase in the work required of the heart consequent on heightened arterio-capillary resistance, valvular disease, overstrain, &c., and (2) impairment of the muscular power of the organ the result of structural disease of the cardiac walls or of nutritive neuro muscular and other disturbances.

In normal conditions the heart may be regarded as an after-loaded muscle, that is to say, its load comes into play only during its contraction. The contractile energy displayed by the left ventricle or, for that matter, by any cardiac chamber at each systole is determined for the most part by the degree of tension of its muscular wall during diastole, and this, again, is regulated by the cardiac tonus. In other words, it is only through the operation of its muscle tonus that the ventricle is kept informed of the work that is required of it. The muscle tonus, though automatic in action, can be increased or decreased through the instrumentality of the central nervous system. Theoretically, an increase in the force of the ventricular contraction can be obtained by diastolic distension of its cavity or by augmentation of its tonus through nervous influences, and no doubt either or both of these means can be brought into operation in practice. These provisions for the regulation and display of contractile energy in conjunction with the reserve power inherent in the cardiac muscle no doubt afford the ventricle a wide range of action within physiological limits. Temporary dilatation of the heart is, however, observed in apparently healthy subjects under the stress of violent or protracted exertion. The additional work imposed on the heart in these circumstances consists, speaking generally, in a transient rise of blood pressure with a largely increased diastolic distension of the ventricles. It seems hardly possible that the contractile energy of the ventricular walls reinforced by their reserve power can become seriously exhausted, more especially as the rise of blood pressure is largely, if not entirely, due to increased output from the ventricles. On the other hand, the tonus of the ventricular muscle must be severely taxed by the excessive diastolic distension, and if in addition the amount of residual blood is increased the conditions for the stretching of the cardiac parietes are no doubt temporarily fulfilled. The action of the fatigue products of muscular activity and also of nervous excitement and exhaustion on the cardiac tonus has also to be taken into consideration. The partial exhaustion of the cardiac tonus would be sufficient to lower the functional efficiency of the heart and to bring about the conditions for the incomplete emptying of the ventricles and for the production of the stretching of their walls and dilatation of their cavities. It must also be borne in mind that in these conditions the ventricles are at an advantage as regards their output with respect to the reduction in size of their cavities by a given volume and this circumstance must afford an additional barrier to the complete breakdown of the contractile energy of the heart. Provided the process does not proceed to the extreme limit of exhaustion of the cardiac tonus the removal of the cause is followed by recovery and restoration of the tonus and of the normal size of the heart.

In those cases, as, for instance, contracted granular kidney, in which increased peripheral resistance is the main factor concerned in the production of dilatation of the heart, the additional work imposed on the organ comes into operation gradually. It is conceivable in these circumstances that the tonus of the cardiac muscle increases, possibly through vaso-motor influences, *pari passu* with that of the blood-vessels, so that the heart gradually grows up to its additional work. Here hypertrophy would not only maintain the heightened tonus but would also provide for the display of increased contractile activity. The subsequent failure of the cardiac tonus, which for the reasons already given would precede the failure of contractile energy, would lead step by step to the yielding of the ventricular wall and to the degradation, by successive stages, of the functional efficiency of the heart up to the fatal event. Otherwise the additional work imposed on the heart would lead by increment of residual blood to increase of the tension of the ventricular wall through augmentation of the cardiac tonus and hence to hypertrophy which would maintain the tonus and amplify the force of the ventricular contraction. The final stages of the process would follow the course sketched under the preceding supposition. This interpretation of the course of events is, moreover, borne out by clinical observation, for the yielding of the ventricle is found to take place step by step and not continuously, which presumably would be the case if the heart gave way in the face of uninterrupted resistance. Acute renal disease is sometimes a cause of rapid dilatation of the heart. Here the sudden imposition of increased work on a weakened ventricle temporarily at least overcomes the cardiac tonus and the heart falls back on its second line of defence which, though it involves some degree of dilatation, gives the organ the time and, if conditions become favourable, the opportunity to recuperate.

The explanation of the mode of development of dilatation of the heart from impairment of its muscular power does not present much difficulty. Here the tonic function of the muscle fibres commences to fail before their contractile energy is seriously impaired, so that the functional efficiency of the heart is degraded step by step through the yielding of its walls. The process is, of course, assisted and consummated by the gradual failure of the contractile energy of the heart. This conception, moreover, is in accord with clinical observation inasmuch as it permits of oscillations in the degree of dilatation and hence of the functional efficiency of the heart—that is to say, the degree of dilatation is decreased or increased with a corresponding rise or fall in functional efficiency according as the influences operating on the cardiac tonus are favourable or the reverse. If dilatation of the heart depended solely on failure of its contractile energy it seems almost inevitable that the cumulative effect of arrears of work in conjunction with the operation of the initial cause of the cardiac failure must lead to a gradual and progressive yielding of the ventricular walls, but in point of fact this is not the case.

An interesting illustration of the working of the hypothesis which I have submitted is afforded by that form of dilatation of the heart which is associated with grief, anxiety, mental depression, and the like. There is abundant evidence of the influence exerted by the nervous system on muscle tonus and the conditions with which we are concerned lead to a reduction of this tonus throughout the body. The heart no doubt shares in the general fall of tonus and the effect on the cardiac wall must be a reduction of the tension of its muscle fibres with a consequent decrease in the display of its contractile energy. Residual blood increases and in the absence of a restoration of the tonus stretching of the ventricular wall and dilatation of its cavity supervene. This process unless checked by a re-establishment of the cardiac tonus may proceed to an irretrievable degree of dilatation and death. Thus, as Sir William Broadbent has remarked, it is almost literally true that people die from a broken heart. If, therefore, the argument advanced in this paper be valid it follows that dilatation of the heart from so-called incomplete emptying depends fundamentally on the same causes as dilatation of the heart from over-filling—that is to say, that both have their origin in absolute or relative loss of the cardiac tonus. It seems *a priori* improbable, having regard to the wealth of the cardiac reserve power, that dilatation of the heart can depend primarily on failure of its contractile energy. Moreover, if this were the case the dilatation, as I have already insisted, should be gradual and continuous, which, so far as clinical observation shows, is not in accord with the usual course of events. On the other hand, tonus is a less stable and more capricious attribute of cardiac muscle than contractility and is therefore more likely to be affected by functional disturbances and morbific influences of all kinds. Furthermore, the operation of a postulated fall or loss of cardiac tonus provides for the production of dilatation, while variations in the display of the function permit of oscillations in the degree of dilatation that is produced. Thus an increase of tonus augments the force and effectiveness of the ventricular contraction and diminishes diastolic distension, whereas a decrease of tonus lessens the force and effectiveness of the ventricular contraction and aids diastolic distension. It is through the agency of these influences, in conjunction, no doubt, with a greater or less degree of modification in the contractile power of the heart, that the amount of cardiac dilatation may vary from day to day and that the organ is enabled to pass through such a wide range of variation as regards the level of its functional activity. The conclusion therefore is that all forms of dilatation of the heart have a common mode of origin, which is found in an absolute or relative diminution or loss of the cardiac tonus.

A few contingent considerations remain which are of sufficient importance and interest to call for a brief notice. The mode of action of the so-called cardiac tonics in the light of the hypothesis advanced in this paper affords scope for speculation and inquiry. The influence exerted on the cardio-vascular system by these drugs, of which digitalis is the prototype, gives rise not only to an increase in the force and effectiveness of the cardiac systole but also to tonic contraction of the arterioles and capillaries in which, of course, the heart shares. It is no doubt to their influence on the cardiac tonus that the beneficial action of these drugs in the treatment of dilatation of the heart must be largely ascribed. For the reasons already given the increase of the cardiac tonus augments the force and effectiveness of the ventricular contraction and the hypertrophy evoked by this additional display of function—which, be it observed, takes place in two directions—maintains the tonus and amplifies the contractile energy of the heart. Cardiac depressants, on the other hand, such as aconite, &c , operate probably in the reverse way—that is, they lower the cardiac tonus and by this means give rise to dilatation of the heart.

In conclusion, it may be pointed out that the hypothesis under consideration has presumably a very wide range of applicability, for if it is competent to explain the mode of production of dilatation of the heart it is also competent to explain the mode of production of dilatation of other hollow muscular viscera—as, for instance, the stomach, intestines, bladder, bronchi, and so forth. In the case of the stomach the question of [illegible] during the first 12 months of [illegible] the gastric tonus have very [illegible] timate size of the organ an[illegible] scular wall. [illegible] ation with hysterical [illegible] ninence the influence [illegible] the intestinal tonus. It is, however, impossible in a paper of this kind to do justice to the interesting and varied problems connected with the mode of production of dilatation of these viscera and I mention them with the object of stimulating inquiry and investigation along the lines suggested by the hypothesis which we have had under consideration.

INTRALARYNGEAL GROWTHS TREATED BY MEANS OF THE GALVANO-CAUTERY.

BY J. DUNDAS GRANT, M.A., M.D. EDIN., F.R.C.S. ENG. & EDIN.,

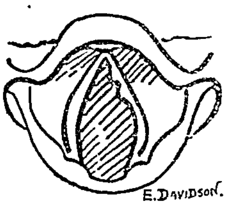
SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL, ETC.

THE final removal of the stump of an intralaryngeal growth is often as difficult as (to the expert) that of the main mass of it is easy. Oliver Wendell Holmes's happy analogy between the elaboration of the last few lines of a poem and the extraction of the last drops of oil out of a bottle is fairly applicable to the case in point. Such, at least, has been the experience of the writer. Many valuable forms of intralaryngeal forceps are at the disposal of the operator and I believe that the form devised by myself for cutting growths off the edge of the vocal cord, the description of which appeared in THE LANCET of June 3rd, 1893, p. 1323, has been in very general use for the intended purpose within the limits which the slightest consideration would impose [illegible] urface of the cord it is, of cours[illegible] the form devised by the late [illegible] st efficacious for those who have been accustomed to Mackenzie's instruments. These are available, also, for many growths in the anterior commissure, though here the snare (so strongly advocated by the late Lennox Browne) has its seat of election. Forceps with the tips bent forwards, according to the designs of Lambert Lack and Fitzgerald Powell, will often clear the anterior commissure when other instruments fail. The extirpation of the residual stump from which re-growth is very apt to take place often baffles instrumental interference as, for instance, when the growth is on the edge of the vocal cord, but so near the anterior commissure that there is no room in front of it for the anterior blade of clean cutting forceps. Such was the case in two instances lately under my care and in them I found in the galvano cautery the means of effecting the final clearance.

CASE 1.—The patient was a comparatively young vocalist and actress whom I brought before the British Laryngological Association in July, 1894, having removed a small fibroma from the right vocal cord at the junction of the anterior and middle thirds. The removal by means of my own forceps was so complete that the patient was enabled to return to her avocation and continued to act and occasionally to sing up to November, 1902, when she came again to me on account of a return of her hoarseness. I found a fibroma on the same spot but more sessile than the previous one and I was able to effect only a partial removal by means of my forceps. I then lightly touched the spot with a fine galvano-cautery point on three occasions with the result that complete disappearance of the growth and perfect restoration of voice ensued. This has continued to the present day.

CASE 2.—The patient was a woman, aged 51 years, who had been practically voiceless for three years. I found a sessile fibroma occupying nearly the whole of the anterior third of the vibratory portion of the left vocal cord and protruding to a considerable extent into the glottic slit. After removal of the main mass by means of my forceps I reduced the growth to dimensions somewhat less than indicated in the figure.

The following is Dr. V. H. Wyatt Wingrave's report as to the microscopical structure:—"The growth consisted of a medullary part composed of fibrous tissue containing small fusiform nuclei with a few large oval nucleated cells (epithelioid) and also some large granular leucocytes. The matrix was homogeneous. The vessels (arteries) showed considerable thickening and were numerous. The surface epithelium was very irregular in arrangement, being corrugated and in parts dipping into the subjacent tissues, but was not fimbriated. It was typical stratified squamous on the surface, the deepest layer being columnar. There was no suggestion of active mitotic nuclear change and no nest or pearl formation. In parts there was some vacuolation. Its nature may be considered as a fibro-papilloma."



The small remaining stump was sufficient to prevent the emission of conversational voice and the application of various astringents seemed to irritate the larynx without producing any diminution in the nodules. In spite of the difficulties in this particular case, to which I shall further allude, I succeeded in touching the stump with the galvano-cautery and after five applications effected its complete removal, the voice becoming clear and strong as it has remained till now (three months later) when the vocal cord is perfectly normal. I showed the case to the Laryngological Society of London in January of the present year.

The difficulties in this latter case were manifold. The patient was a somewhat rotund personage with an extremely protuberant "bust" and a short neck, so that there was little room for the hand of the assistant holding out the tongue and of the one holding the Mount-Bleyer or Escat tongue depressor, which the pendulousness of the epiglottis rendered necessary. In addition, the tongue was large in proportion to the size of the buccal cavity even when the artificial teeth were removed. It was difficult even to introduce the laryngeal mirror. Finally, the epiglottis was pronouncedly "pendulous" and only very fleeting views of the seat of the disease were obtainable. It must be stated to the patient's credit that her good-will and patience were most exemplary. The introduction of my forceps required the exercise of some force and the manipulation inside the larynx was necessarily carried out *à l'aveugle* in a way which would have been scarcely possible with a less guarded instrument. The use of the galvano cautery had to be practised on totally different lines. For this the most complete illumination was necessary, so that the application should be made under the guidance of the eye. For this purpose I made use in the first instance of Mount-Bleyer's epiglottis lifter, the tip being placed in the vallecula in front of the epiglottis, the pressure therein causing this to rise up so that the anterior part of the glottis could be plainly seen. I found, however, that Escat's instrument caused less discomfort and in this particular case permitted of as good a view of the larynx being obtained. I was thus enabled, after cocainisation, to overcome the difficulties I have mentioned and to effect the application of the galvano-cautery.

The cautery itself must answer certain requirements. It must be of [illegible] the particular spot in the [illegible] e it should be introduced [illegible] nd length (of vertical portion) until it can be made to touch the exact spot with as little difficulty as possible. Again, it should be instantly responsive to the make and break of the current. I use Schech's handle and frequently renew the points which Schall carefully files down for me at the extremity till the incandescence and extinction are practically instantaneous. The extent to which the cautery has to be bent down is sometimes more considerable than would be anticipated. In Case 1 the bent-down portion was fully four inches in length, and I have at present under my care a patient on whose left vocal cord was a large sessile papilloma which I was unable to reach by means of my longest laryngeal forceps, but which I have succeeded in reducing almost to a vanishing point by the use of the galvano-cautery bent down to as great a length. For such a small stump as I have described the lightest touch is all that is desirable and ought indeed to be much less than at the time appears sufficient. In addition to the destruction of a portion by the actual burning away of substance the subjacent part of the growth undergoes a certain amount of shrinkage. Complete burning away of the growth would therefore be attended by a risk of undesirable cicatrisation of the normal underlying structures.

I do not wish it to be inferred that in these manipulations I have never touched the normal neighbouring parts of the larynx. In Case 1 I certainly did avoid doing so; in Case 2 I more than once cauterised the superjacent portion of the ventricular band and also the opposite vocal cord. In the third case to which I have made reference the patient was exceptionally restless besides being absolutely intolerant of the "epiglottis-lifter" and I slightly cauterised the laryngeal surface of the epiglottis. As a rule I was able to confine the momentary cauterisation to the desired spot and in no instance did the involvement of the adjacent parts mentioned occasion anything approaching obstructive œdema or indeed any symptom beyond a slight increase of hoarseness, which rapidly subsided.

With the precautions I have mentioned I believe that we have in the galvano-cautery an instrument which might be more frequently employed for the purpose under consideration than appears to be usual.

Cavendish-square, W.

A NON-TOXIC PREPARATION OF IODINE.

By V. H. WYATT WINGRAVE, M.D. Durh.,
M.R.C.S. Eng.,
PHYSICIAN TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

BEING especially interested in the supplemental treatment of enlarged glands and adenoids with iodine, about seven years ago I made several experiments with preparations of that drug with the object of finding one which could be given internally in large doses for considerable periods without causing symptoms of iodism while exercising its specific effects on lymphatic enlargements. The late Mr. Martindale and the manager of Messrs. Morson and Sons were good enough to try several formulæ for me in their laboratories and finally succeeded in producing an easily-made compound in which iodine was loosely combined with an organic substance, rendering it fit for ready absorption without causing any irritation of the digestive canal and affording a high physiological activity without any evidence of intolerance. This preparation I have used ever since both in hospital and private practice, and having watched the effects have come to the conclusion that it has fully confirmed my first estimate of its value.

The formula which I now employ has been perfected for me by Mr. W. H. Martindale, is easily prepared, and is very palatable. The iodine is in loose chemical combination with tannic acid, since none can be demonstrated as free, yet it is sufficiently free to be given up readily to the tissues after absorption and consequently there is no chance of any local intestinal or gastric irritation, so often associated with the administration of *free* iodine. Such combination is one of a nature similar to that of oxyhæmoglobin. Formula:—iodine, 2½ grammes; tannic acid, 4 grammes; alcohol (90 per cent.), 38 cubic centimetres; syrup, q s. to 75 cubic centimetres. The iodine is dissolved in the alcohol, the tannic acid and 30 cubic centimetres of the syrup are added, the solution is heated to just below boiling point until it affords no evidence of free iodine with the starch reaction (about 20 minutes), is then cooled, and the remainder of the syrup is added with flavourings. Each drachm contains two grains of iodine. It may be given in doses of from half a drachm to two drachms in water or wine before meals according to age.

I have found that children tolerate it well and it has proved specially useful in cases of chronic lymphadenitis associated with, or independent of, enlarged tonsils and adenoids, especially when the enlarged cervical glands persist after tonsillotomy. It is further indicated in those children who possess but slightly enlarged faucial and pharyngeal tonsils in whom operation is contra-indicated or objected t In atrophic rhinitis it has afforded gratifying resul especially when combined with arsenic; also in simpl bronchocele supplemented with the use of iodine oleate (in 9 of oleic acid) as a pigment.

Such an organic combination of iodine is by no means ne as it was introduced many years ago in the form of a wine—"Vin Nourry"—but so far as I know no definite or simpl formula suitable for prescribing purposes has been availabl It is for this reason and for the very satisfactory result which it has afforded in a prolonged trial that I venture t recommend it.

A Mirror
OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Procemium.

THE FRENCH HOSPITAL, SHAFTESBURY AVENUE.

SIX CONSECUTIVE CASES OF DISEASE OF THE FALLOPIAN TUBES.

(Under the care of Dr. SEPTIMUS SUNDERLAND and Mr. EDMUND OWEN.)

FOR the notes of the cases we are indebted to Mr. Jehan M. Barlet, resident medical officer.

CASE 1. *Double tubo-ovarian abscess.*—A married woman, aged 39 years, who had borne no children, was admitted into the French Hospital on Oct. 8th, 1903, for pain in each ovarian region. She had had gonorrhœa and had been in the French Hospital two years previously with the same symptoms. On vaginal examination a semi-elastic swelling of about the size of a hen's egg could be felt on the right side, but nothing definite could be made out on the left, though she complained of more pain on that side.

Mr. Owen made a three-inch incision in the median line and finding the right ovary and tube enlarged removed them, the tube rupturing under the manipulation and pus escaping. The soiled viscera were carefully wiped over but no irrigation was employed. The left ovary and tube were also diseased and were removed. A drainage-tube was left in for 48 hours. The woman made an uninterrupted recovery.

CASE 2. *Double tubo-ovarian abscess.*—A woman, aged 32 years, who had been married ten months and had had no children, was admitted into the French Hospital on Nov. 11th, 1903, for pain over each ovary. For six months previously she had had pain in the right iliac fossa, there being a history of a diminution of the menstrual flow for two months, followed by an advance of the period by 15 days, lasting 15 days. Her husband had had gonorrhœa.

A three-inch median incision was made. The left tube was much dilated and the ovary was enlarged; they were removed. The right tube and ovary were then brought to the surface and also found to be diseased and were likewise removed. (On opening the tubes subsequently pus was discovered in each) A drainage-tube was left in for 48 hours. She also made an uninterrupted recovery.

CASE 3. *Encysted purulent peritonitis secondary to pyosalpinx.*—A woman, aged 30 years, was admitted into the French Hospital on Jan. 20th, 1904, for abdominal pain. There was a large swelling in the right iliac fossa. There was a history of pains in the lower abdomen during six years; they had usually passed off with rest and douches. 12 days before admission she had been seized with severe pains and had passed a dark clot of blood per vaginam. She said that she had had a temperature going up to 103° and 104° F. and also that a large swelling had begun to form in the right lower abdomen. On admission she was looking ill; she vomited. The pulse was 124 and the temperature was 100°. The abdomen was distended, especially on the right side. There was a limitation of respiratory moveme [illegible] A large swelling could be felt in the right [illegible] upper part of the tumour. On vaginal examination a hard [illegible] fornix, the uterus being [illegible] ual examination fluctuation was obtainable; the mass was fixed.

Mr. Owen opened the abdomen on the day following her admission by a median incision below the umbilicus. The small intestines were congested, covered with lymph, and adherent to [illegible] of foul-smelling pus [illegible] out with abundant hc [illegible] bes were brought out by counter openings, but the case seemed hopeless. The source of the pus could not then be discovered as all the tissues were closely matted together. The patient was very much collapsed after the operation but by [illegible] She died early on [illegible] vere matted together [illegible] and the uterus was an abscess containing about ten ounces of pus, which had not been discovered at the operation. There was pus in the right Fallopian tube and ovary, and in the body of the uterus was a *large, deep ulcer which encroached upon the opening* of the right Fallopian tube. At one spot the wall of the bladder was ulc [illegible]

CASE 4. *Ec* [illegible] years, who had had [illegible] French Hospital on [illegible] lower abdomen on the right side. Her history was as follows: On Christmas Day, when walking with her husband, she was suddenly taken faint and had to be carried home. From that time she had been constantly losing blood. The pain continued and she had neuralgia down the inside of the thigh. She frequently vomited. There was no history of gonorrhœa. The temperature was normal. Examination showed that there was acute tenderness over the region of the right ovary, a resistance being distinguishable The uterus was moveable and the os was capable of admitting the tip of the index finger. Against the right fornix a tender, moveable, semi-elastic swelling, [illegible] shed.

[illegible] ches long, [illegible] cavity. A [illegible] the right [illegible] to the sur- [illegible] The tube [illegible] at was tied off and the mass was removed. On cutting into it a large blood clot was found associated with a ruptured tubal gestation. There was also a small cyst of the ovary. The pelvis was wiped clean of blood and the wound was closed. A few weeks later she was sent to the convalescent home at Brighton.

CASE 5. *Right pyosalpinx; left suppurating ovarian cyst.*—A woman, aged 27 years, married, with no children, was admitted into the French Hospital on Jan 15th, 1904 She had [illegible] tant pain in the [illegible] in menstruation [illegible] had had three [illegible] years previously she had a [illegible] associated with pains which had [illegible] all these years. She had been [illegible] ouches and rest but without material advantage. Vaginal examination showed that the uterus was fixed and thrust backwards by an elongated mass on the left side, which was also fixed to the rectum and bulged against the left fornix. On the right side was a moveable, semi-elastic swelling of about the size and shape of a hen's egg and partly posterior to the uterus.

[illegible], the right tube was [illegible] ding tissues; these [illegible] the swollen and con- [illegible] lymph, was brought to the surface, tied off, and removed The left tube was made out with difficulty, as it was concealed by, and was closely adher [illegible] the rectum, and [illegible] at length been [illegible] age was brought to the surface, secured, and removed. There was a good deal of oozing, the blood being mopped out with sponges soaked in a very hot saline solution. A Keith's tube was inserted and the abdominal wound was sewn up. The drain was removed after 48 hours, there being only a slight [illegible]. The temperature remained [illegible] e above 84 per minute. On examining the masses removed the one on the right side proved to be a pyosalpinx, whilst the one on the left side had the appearance of an ovarian cyst which had suppurated. She made a rapid recovery.

CASE 6. *Right salpingitis and cyst in the broad ligament; left salpingitis.*—The patient, a widow, aged 24 years, was admitted into the French Hospital on Feb. 1st, 1904, for great pain in the right iliac fossa. She had had no children but had one miscarriage four years before. A week previously she had been wrestling and on the next day she felt an acute stabbing pain in the right iliac fossa, which doubled her up and, as she says [illegible] pain. At the time of her violent e [illegible] of her monthly period, and after [illegible] increased very considerably, with [illegible] had always been regular. The a [illegible] with respiration, except in the l [illegible] was a slight resistance on the right side. Vaginal examination showed that the os was patulous and that the uterus was definitely enlarged and pushed over to the left side by a semi-elastic swelling which bulged down against the right fornix. *It seemed to be of about the size of a small orange.* Above this could be felt a distended tube There was free discharge of blood from the uterus. Dr. Sunderland had seen her in consultation at her own house and, recognising the presence of an acute pelvic condition which evidently needed exploration, sent her into the hospital for operation. This was performed on the following day. Colonel C. H. Joubert, I M S., late professor of obstetrics at the Calcutta Medical College, was present at this operation.

A median incision having been made, there was found on the right side a dark and adherent mass which proved to be the distended Fallopian tube; below this a cyst was found as big as a small orange lying between the layers of the broad ligament in close connexion with the enlarged Fallopian tube. The cyst burst on being freed from adhesions, discharging a thin sanguineous fluid. The whole mass was tied off in sections and removed. On the left side a slightly enlarged tube showing evidence of salpingitis was found behind the uterus and removed. The oozing from [illegible] adhesions was stopped with sponges wrung out [illegible] be was left in for 24 h [illegible] which had appearances suggestive of an extra-uterine gestation, was sent to Dr. G. Leslie Eastes for examination who reported as follows: "This specimen shows the presence of thrombosed vessels, and free hæmorrhages in the walls of the tube, together with a large amount of granulation tissue. Chorionic villi have not been found, so that tubal gestation cannot be diagnosed We must conclude that the intramural hæmorrhage was due to some acute condition supervening upon a chronic inflammatory process" The patient, who strenuously denied the possibility of ectopic gestation, made an uninterrupted recovery.

Remarks by Dr. SUNDERLAND and Mr. OWEN.—The misapprehension that gonorrhœa is not a very serious disease is widely spread. It has been argued that though it is a common affection of young adults one rarely hears of a man being permanently damaged by it, provided only he has escaped being the subject of organic stricture of the urethra and the various diseases of the bladder and kidneys which may depend upon it. But the surgeon who sees a patient with secondary gonococcal inflammation of the knee-joint or of a series of joints, and the physician who is called to advise in the treatment of a [illegible] tion of the pericardium has [illegible] venereal urethritis, cannot fail [illegible] as one of extreme potentia [illegible] saddest, as well as the most [illegible] of gonorrhœa are met with in the case of the married woman whose life is rendered miserable and uncertain by infection which was unwittingly communicated to her by her husband. The probability is that the man honestly believed himself to be, and was duly advised that he was, perfectly cured of his urethritis at the time of his marriage, when, as a matter of fact, gonococci were still present in the urethral canal It is quite possible, moreover, that the wife was infected with the micro organisms without realising that there was *anything seriously* amiss with her, that the area of incubation of the micro-organisms was chiefly confined to the interior of the cervix uteri, for instance, and that she had none of the usual symptoms of gonorrhœal infection. It not infrequently happens that when the practitioner has asked all the questions which he deems it prudent to put to the wife, he leaves off his cross-examination without having obtained collateral evidence of her having been definitely infected, though the confessions of the husband and the circumstances of the case leave little room for doubt.

Of the four cases of pyosalpinx reported above, Nos. 1 and 5 gave a clear history of gonorrhœal infection; No. 3 had probably been a victim to it, and No. 2 might well have been infected from her husband. No. 3 is one of those sad cases in which infection spreads from a tubal abscess to involve the peritoneum in a fatal suppuration. Bacilli coli communes must have been present in myriads, the original tubal swelling having been probably infected from adherent intestine. The history of this case adds further support to the teaching of those who advise that in all cases in which the existence of a tubal abscess is suspected the tumour should be explored without delay by abdominal section, and then dealt with in the only possible way—that is, of course, by removal.

Another point for remark is that if in the process of being separated from the surrounding adhesions the cyst gives way and its foul contents spread themselves over the adjacent coils of intestine, the most practical manner of cleansing these is by the free use of dry absorbent sterilised swabs. Formerly it was very much the custom to deal with the soiled viscera by hot flushings, but though in cases where the pus was not sterile this method could not be depended upon to wash away all the germs it was certain to convey some of them to parts of the serous membrane which, up to that time, they had not reached. In operations in which the foul contents of an appendicular or a tubal abscess unavoidably find access to the serous covering of neighbouring viscera, is not the simple process of wiping the part clean with a soft dry sterilised swab as likely to prove efficient as the less convenient one of irrigation? In every case the surgeon should do his best to prevent the occurrence of any fouling, but if, notwithstanding, it does occur and the case turns out successful nevertheless, he must not ascribe all the credit for the happy result to the way in which he dealt with the straying pus.

What is the explanation of the favourable course which cases often run when the surgeon has concluded his operation with the full knowledge that pus has been left behind? It is possible that the escaping pus was sterile. In other cases where pus which contained bacilli escaped upon and contaminated the peritoneum and no worse results followed than a slight localised peritonitis, it is probable that the formation of leucocytes and plasma-cells on the peritoneal surface prevented the entrance of the poison to the system. Possibly, also, during the time that an abscess was forming an antitoxin was being prepared in the blood which sufficed to render harmless the occurrence of, or even to prevent, a localised peritonitis. Therefore, when there is no urgent indication for immediate operation it is advisable to prepare the patient for the operation by rest in bed, good feeding, and a course of ferruginous tonics so that the blood cells may be the better able to resist the ravages which might be caused by bacilli-laden pus if the tubes happen to rupture during the operation.

In 1899 Mr. A. G. R. Foulerton reported the results of 459 cases of salpingitis (including 16 cases investigated by himself) in which the pus had been examined by competent observers. In about 20 per cent. of these cases the gonococcus was discovered, in about 20 per cent. bacteria other than the gonococci were found (including the staphylococcus pyogenes albus, the bacillus coli communis, the bacillus tuberculosis, and the streptococcus pyogenes), but in the remaining 60 per cent. the contents of the tubes had been found absolutely sterile. He explained this absence of bacteria by the fact that many cases of pyosalpinx are not operated upon till a considerable period after the formation of the abscess, by which time the causative parasites have perished as the result of starvation or of being poisoned in a small closed cavity by their own excretory products. With regard to the 20 per cent. of cases in which other bacteria than gonococci had been found, in a certain proportion of them the bacillus discovered did not always harmonise with the etiology of the disease, for in some of them the pus had become sterile and had been secondarily infected with the bacillus coli communis from adherent intestine. It is thus impossible to determine from examination of the pus contained in the tubes the proportion of cases which owe their origin to gonorrhœa. But it is our opinion, judging partly from the records of Mr. Foulerton and partly from our own clinical experience, that the number of cases of pyosalpinx which owe their origin to gonorrhœa is considerably under-estimated and that the proportion given by text-books of a percentage of from 20 to 30 is far below the mark.

In a case of salpingitis arising during an attack of gonorrhœa when there is evidence that pus has formed in one or in both tubes the questions arise: Should the condition be dealt with per vaginam (through Douglas's pouch), as recommended by some surgeons, or by laparotomy? And, secondly, when should operation be undertaken? In our opinion cases in which incision and drainage of the tube through the vagina should be resorted to must be of very rare occurrence. When there are much matting and adhesion it must be difficult to insure that all the pus has been evacuated, and certainly it seems a more sound principle to remove the whole of the diseased tube by laparotomy, as in the case of intrapelvic abscess due to disease of the appendix cæci.[1] With regard to the time for operation, it is probably wise to allow the patient to get over the acute inflammatory attack and unless urgent symptoms should call for interference to wait for a few months until the virulence of the contents of the tubal abscess may have abated in order to minimise the risk of infecting the peritoneum. It is impossible to lay down definite rules, for the circumstances of each case have to be considered. Indeed, some of these cases if left alone get well without operation, the pus apparently becoming absorbed.

In conclusion, we would like to insist upon the importance of the careful and thorough treatment of gonorrhœa in females in its initial stage. This cannot be too strongly put forward when one considers the amount of suffering and the risk to life which may attend upon an apparently slight attack of the disease.

Medical Societies.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on March 18th, Dr. Percy G. Lewis being in the chair.—Mr. Harold Burrows showed a case of Enlarged Liver and Spleen in a girl, aged 13 years. Six months previously laparotomy had been performed for supposed hydatid disease of the liver but the liver was found to be uniformly enlarged and smooth. There was no history of syphilis but as there were the remains of old retino-choroiditis in both eyes a diagnosis of syphilis had been made.—Dr. C. W. Chapman showed a girl, aged 12 years, who had suffered from Mitral Disease with recurrent attacks of Dilatation of the Heart. These had at first yielded to the ordinary remedies but later the dilatation and failure of compensation which were accompanied by orthopnœa were not relieved until solution of adrenalin was administered in five-drop doses every four hours. This was followed by steady improvement.—Mr. J. Keogh Murphy showed a case of Hæmatoma of the Parietal Bone in an infant, aged eight weeks, and a case of Double Pes Cavus in a boy, aged four years.—Dr. Leonard G. Guthrie showed a boy, aged 11 years, who for two years had been subject to peculiar attacks in which he would suddenly run to his mother, exclaiming, "Horrid smell." He would appear much agitated and distressed for a few moments, sometimes spitting and grimacing, and going through the action of trying to pull something out of his mouth. He would then behave "as if he were silly," running to persons in the room and trying to embrace them. After five or ten minutes of this behaviour he would become quiet, turn pale, shiver as if cold, seem exhausted, and lie down to sleep. Dr. Guthrie regarded the case as one of automatism with olfactory and gustatory auræ, a condition allied to epilepsy or megrim. Under treatment with bromide of potassium in eight grain doses thrice daily the attacks diminished rapidly in frequency and severity.—Dr. Lewis commented on the large pupils and a tendency to exophthalmos in the patient.—Dr. E. A. Jones said that visual auræ were of two kinds, either of persons which were usually unpleasant, or of landscapes which were usually pleasant.—Dr Edmund Cautley showed a case of Multiple Congenital

---

[1] Brit. Med. Jour., Feb. 20th, 1904, p. 426.

Deformities in a girl, aged five years. She was one of 12 children, all the others being healthy and well formed. She was very small and intellectually deficient. Walking or standing had not yet been accomplished, although there was no indication of muscular or nervous lesion. The eyes were marked by notching of the upper lids, dermoid cysts on the conjunctivæ, coloboma of the iris and choroid, and choroidal atrophy. There were accessory auricles and macrostoma on the right side.—Mr. J. P. Lockhart Mummery said that the association of auricular appendages with the fissure of the mouth was interesting because those cases seemed to support the theory that the auricular appendages were developed around the outer end of a partly persistent inter-maxillary cleft, the anterior part of which was represented by the fissure of the mouth.—Mr. J. Howell Evans pointed out that the notch in the upper eyelids occurred at a point where there was a division between the nerve-supply of the outer two-thirds and the inner third, a situation often occupied by birth-marks and moles.—Dr. G. A. Sutherland showed a boy, aged eight years, suffering from Chronic Interstitial Nephritis and commented on the syphilitic origin of these cases although there was no history of that disease in the present instance. There was marked cardiac hypertrophy and the radial arteries were thickened. The urine was of low specific gravity and contained occasionally a trace of albumin and granular casts. There were no retinal changes.—Dr. E. P. Baumann showed a specimen of Early Parrot's Nodes from a child, aged two years. The nodes were in an early stage, being small, sharply limited, and still vascular. It was uncommon to find them *developing* at such a late age. The patient had well marked signs of syphilis.—Dr. George Carpenter said that he regarded Parrot's nodes as definite evidence of syphilis and that the spleen would usually be found to be enlarged in such cases.—Mr. Sydney Stephenson read a paper on Congenital Word-Blindness in Children.—Dr. J. Porter Parkinson and Dr. Douglas Drew communicated notes on a case of Nephrolithotomy.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 18th, Dr. D. Newman, the President, being in the chair.—Professor McCall Anderson showed three cases of Lupus which had been treated for long periods with the x rays with no improvement. Professor Anderson proposed to treat the cases with tuberculin and he intended to show them to the society after undergoing a course of that treatment.—Dr. W. S. Syme made a brief communication on Chloride of Ethyl as a General Anæsthetic for short operations on the throat and nose. He demonstrated a simple inhaler and with this inhaler the results compared favourably with those obtained with more elaborate inhalers. He claimed for ethyl chloride the following advantages. With a single administration, the dose varying according to the age of the patient and the time required, a period of anæsthesia up to two and a half minutes might be confidently expected. There was a minimum of struggling, so that, as in some of his cases, the assistance of a nurse was sufficient. The patient quickly recovered and the after-effects were slight. If vomiting did occur it was of short duration. Chloride of ethyl came next to nitrous oxide in safety. The dose he recommended was from three to eight cubic centimetres though more might be given if necessary.—Dr. G. H. Edington showed: (1) A specimen of Undescended Testicle, showing Tubercles in the Processus Vaginalis; (2) a specimen of Testicle fully descended strangulated by torsion of the pedicle; and (3) Solitary Kidney with Dilated Ureter associated with Malformation of Generative Organs, Ribs, &c., from a case of Atresia Ani.—Dr. J. Hinshelwood reported a case of Congenital Word-blindness.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on March 23rd, Dr. J. Nigel Stark, the President, being in the chair.—Dr. J. M. Munro Kerr showed: (1) A Myomatous Uterus with a large Multilocular Ovarian Cyst; (2) an Ovarian Cyst with the pedicle twisted three times; (3) Pyosalpinx; and (4) a Pregnancy situated either in the interstitial portion of the tube or in one half of a double uterus.—Dr. E. M. Pace showed a Fibroid Tumour of the Uterus undergoing Myxomatous Degeneration. There was also myxomatous tissue in the broad ligaments.—Dr. R. Jardine showed a Curette for the Treatment of Abortions. The edge was sharper than that of the ordinary dull curette.—Dr. Jardine also read notes of a case of Ulcer of the Stomach after removal of a large ovarian cyst. The cyst was complicated by the presence of a fibroid tumour of the uterus, which, however, was not removed on account of the debilitated condition of the patient. On the second day after operation the patient collapsed. The motions after this were dark, like altered blood. On the twelfth day collapse again occurred, followed by coffee-ground vomiting. The patient ultimately made a good recovery.—Dr. Carstairs C. Douglas said that in some such cases where death took place no gastric ulcer was found on post-mortem examination and suggested that this was a case of post operative hæmatemesis.—Dr. Jardine replied that post-operative hæmatemesis occurred within a few days of operation, whereas in his case the second attack of collapse set in on the twelfth day.—Dr. W. L. Reid gave an estimate of the Relative Merits of Ventrofixation and certain other Operations for the Relief of Uterine Prolapse and Retroflexion. Dr. Reid said that if a prolapse or retroflexion, in which latter term he included retroversion, was capable of being so modified as effectually to relieve the patient by the use of a pessary he usually contented himself with recommending it, more especially as a permanent cure often resulted. Where pessaries failed and where there were no adhesions shortening of the round ligaments frequently did well. He had largely given up this operation, partly on account of the difficulty of performing it, partly because of the danger of hernia, and partly because of the appreciation of other operations. The next method he favoured, for prolapse only, was anterior and posterior colporrhaphy. To be trustworthy this had to be done thoroughly. If the uterus was heavy it was well also to amputate the cervix. Later, in young women likely to bear children he had begun to perform hysteropexy.

ROYAL ACADEMY OF MEDICINE IN IRELAND: SECTION OF PATHOLOGY.—A meeting of this section was held on March 18th, Dr. H. C. Earl, the President, being in the chair.—Mr. E. H. Taylor and Dr. O'Sullivan exhibited a Tumour from the leg of a man, aged 42 years, which had originated a year previously in a mole. The tumour, which was attached by a pedicle, was pigmented and had grown very rapidly. The glands in the inguinal region and in the iliac fossa were large and hard. Dr. O'Sullivan demonstrated microscopic preparations from various portions of the tumour. It showed near the periphery spaces lined by a single layer of high cubical cells separated from blood-vessels by hyaline connective tissue. In a deeper portion the cells, several layers deep, had encroached in this connective tissue and formed a sort of outside sheath to the vessels. The main part of the growth consisted of solid columns of cells separated from one another by a fine fibrous stroma. These cells showed very numerous mitoses. The pigment was confined to the stroma. Dr. O'Sullivan considered the tumour to be an endothelioma growing from the lymph spaces in the subcutaneous tissue.—The President discussed the paper.—Mr. L. G. Gunn showed *two Tumours from* Kidneys of Different Subjects. One which he called a sarcoma showed large round cells invading the kidney substance. He discussed the possibility of the tumour being a carcinoma of the suprarenal capsule. The second tumour showed a firm cystic structure with a papillary growth extending into, and dilating, the ureter.—The President and Dr. O'Sullivan spoke.

NEWPORT (MON.) MEDICAL SOCIETY.—A meeting of this society was held at the Newport and County Hospital on March 30th, Dr. J. Howard-Jones, the President, being in the chair.—Dr. R. J. Paton showed a specimen of Encysted Hæmatocele of the Cord.—Mr. J. McGinn read a paper on the Value of Venesection in Over-distension of the Right Side of the Heart and quoted his own favourable experience of the treatment.—Dr. J. Batten Coumbe read a very able and interesting paper on the Nature and Action of Toxins and Antitoxins.—The specimen and papers were fully discussed by the members present.—Mr. W. Bassett drew attention to the recent circular of the Medical Defence Union with regard to the proposed medical defence branch of the British Medical Association and it was decided to hold a meeting in April to discuss the subject.

BRENTWOOD CONVALESCENT HOME FOR CHILDREN.—On Thursday afternoon, April 14th, the new building of this institution will be opened by Lady Rayleigh. A short opening service by the Bishop of Colchester will be held previously.

Reviews and Notices of Books.

Vaginal Tumours, with Special Reference to Cancer and Sarcoma. By W. ROGER WILLIAMS, F.R.C.S. Eng. London: John Bale, Sons, and Danielsson, Limited. 1904. Pp. 92. Price 5*s.* 6*d.* net.

THE subject of vaginal tumours has hitherto not received much attention from English writers and this valuable monograph by Mr. Roger Williams is an attempt to collect and to coördinate the details with regard to these tumours which exist scattered throughout medical literature. The book includes a consideration of all the different forms of vaginal tumours, special reference being paid to cancer and sarcoma. The author agrees with Nagel's views as to the development of the vagina from the Mullerian ducts and does not accept Berry Hart's theory of the part played by the so-called Wolffian bulbs. He is also inclined to agree with the theory of Davidsohn that the small cysts lined with cylindrical epithelium found in the upper part of the vagina are aberrant offsets of the cervical glands. It is curious to note that in spite of its rarity cancer of the vagina is the commonest of the primary vaginal neoplasms, although its frequency of occurrence amounts only to about 0·43 per cent. of all carcinomata in women—a rate of frequency which is a most powerful argument against the view that irritation plays any part in the production of such growths, for few parts of the body are so liable to irritation as the vagina. The posterior vaginal wall is by far the most frequent seat of growth, 50 of the 76 cases tabulated by Bernard arising in this position. The disease is of the most fatal character, for of 16 cases operated upon in Olshausen's clinic in no less than 15 the disease soon recurred. The infantile type of sarcomata are considered to arise from developmental irregularities occurring more especially in connexion with the development of the cloaca. The great majority of these tumours are found in infants, no less than 17 out of the 25 collected by Gatti being of this variety. Details are given of a number of cases illustrating the main features of these interesting growths. In a short description of "vaginal polypoid formations in infants" attention is called to the fact that these tumours are often erroneously referred to as examples of congenital vaginal myomata. Primary melano-sarcoma of the vagina is of the utmost rarity but two cases recorded by Horn and Parona are related by Mr. Williams.

In considering the important question of the occurrence of deciduoma malignum in the vagina the author gives it as his opinion that instances of this disease occurring independently of pregnancy have not been substantiated and he sees no reason for resorting to such a far-fetched hypothesis as that of "fœtus in fœtu" to account for these tumours.

There seems little reason to doubt that the great majority of so-called fibroid tumours of the vagina are really myomatous in origin. This was probably so in no less than 19 out of the 29 recent cases tabulated by Phillips. The section devoted to cysts of the vagina is of particular interest and the author recognises no less than seven different modes of origin for these tumours—viz , from the Wolffian or Müllerian ducts, cysts derived from "rests" of the mucosa of the uterine cervix, cysts derived from "rests" of the vulvar mucosa, dermoid cysts, endothelial cysts, and parasitic cysts. There can be no longer any doubt that cysts arise from "rests" of both the Wolffian duct and the Wolffian body. The cases recorded by Routh, Skene, Milton, Rieder, and others prove this. Freund was the first to suggest that certain cysts of the vagina arose from the "rests" of the Mullerian ducts and he has recorded tumours of this kind occurring in the vaginal portion of the cervix and the upper part of the vagina. The "glandulæ aberrantes cervicales" described by Davidsohn no doubt represent the so-called vaginal glands of Huguier, Hennig, and others. Vaginal cysts, apparently arising from these glandular structures, have been described both by Davidsohn himself and by Poupinel. Vaginal cysts in the neighbourhood of the vulva undoubtedly take origin, in some instances, from "rests" of the vulvar mucosa. Although so little has been written on this variety of vaginal tumour, yet, as the author shows, dermoid cysts of at least three kinds occur in the vagina—viz., implantation dermoids, true dermoids, and dermoids derived from "rests" of the vaginal epithelium. A short final section is devoted to the interesting question of hymeneal cysts.

The extracts we have given show with what thoroughness Mr. Williams has discussed his subject. This little work is full of facts and information and should prove of the utmost value to the gynæcologist and to the general practitioner.

La Peste: Étude Critique des Moyens Prophylactiques Actuels. (The Plague: Critical Study of the Present Prophylactic Measures.) By Dr. J. Th. DUPUY. Paris: F. R. de Rudeval. 1904. Pp. 158. Price 2 francs.

La Fièvre Jaune. (Yellow Fever.) By Dr. J. Th. DUPUY. Paris: F. R. de Rudeval. 1904. Pp. 85. Price 2 francs.

IN his work on plague Dr. Dupuy gives us a critical study of the methods of prevention that may be carried out not only in the port of arrival but also in the interior of the country affected. The author anchored in the harbour of Monte Video with a clean bill of health in April, 1902, when news came that Buenos Ayres, the port to which his ship was bound, was affected with plague. After eight days the vessel left Monte Video for France, her sanitary state having been certified to be excellent, and in three weeks she arrived at Marseilles. During the subsequent disembarkation no dead rats were found. A week after her arrival, however, a mortality amongst these animals set in, when the ship was disinfected with sulphur. About a week afterwards two of the crew were seized with the disease, one of whom died. The ship was ordered to the lazaretto at Frioul. Such was the history of the onset of the affection. Dr. Dupuy then details the measures that were taken during the quarantine of the vessel as regards disinfection. All communication with the shore having been stopped, the ports were closed and fumigation with sulphur was carried out, after which they were opened and free perflation of air was allowed. Any dead rats found were collected and burnt. A general disinfection of the crew was effected and all who desired it were inoculated with prophylactic serum, a dose of six cubic centimetres being given, the men who had come into contact with the rats being especially urged to undergo the inoculation. At the lazaretto there were two other steamboats affected. Inoculation of their crews was also resorted to; no untoward result followed beyond an eruption like that of scarlet fever or an erythema around the point of injection in three or four of the men. The vessel was then attended to, the mattresses and linen being subjected to hot air; the ports were then closed and the holds and passages were fumigated also with hot air for several hours, whilst the sails, forecastle, and various parts of the ship were washed with sublimate. Sulphate of copper, 5 per cent., was placed in the bilge. Next, in the proportion of 50 grammes for each cubic metre, sulphur was placed in receptacles and lighted with alcohol, all doors and other apertures being closed for 36 hours. The bakery and slaughter-house were washed with sublimate, 1 in 1000. Finally, after a second disinfection of the holds with sulphur and a washing with sublimate from the hose, the ports were opened. Thus, to sum up, all the parts of the vessel below the water line were fumigated with sulphur dioxide and then washed with a solution of 1 in 1000 sublimate; all above the water line were treated twice with the sublimate. The engine room was washed with 5 per cent. cresyl. 27 rats were found asphyxiated by the sulphur dioxide and were burnt.

Observations on 170 individuals who were injected with the prophylactic serum of Yersin, the dose being six grammes, showed not the slightest bad effect. The strictest antiseptic measures were taken No cutaneous eruption or fever appeared; the only thing observed was slight nervous apprehension amongst a few.

The latter part of the work contains some remarks on the results of protective inoculation in 44 individuals Here also no untoward effect followed. Four showed localised œdema in different places, whilst one had a generalised urticaria, but whether this latter was due to the injection or to his having previously eaten largely of fish, "bouilla baisse," could not be determined. In his survey of the operations Dr. Dupuy states that the principal conclusion at which he arrives is that they will always take an "enormous" time. He remarks that the length of quarantine imposed on any vessel is six days, whereas his operations of disinfection took 12 days, although the attending circumstances as regards the *personnel* for the carrying out of the necessary measures were remarkably favourable. Had they not been so the time necessary for their completion, he considers, would have been doubled. Of the means of disinfection he thinks that by sulphur to be the best and the most suitable. He comes to the conclusion that the contagion of plague is as a rule feeble and that we are better armed against it than against the majority of our great endemics. This, however, from the experience in India, would not seem to be in every case the fact.

In the second volume under review, Dr. Dupuy details the interesting results of his personal observations on yellow fever. In August, 1899, he reached the roadstead of Dakar and found a notification there to the effect that yellow fever had occurred in Rio Janeiro, where it had raged with great severity from April to the commencement of July, Bahia being also affected, these two ports being most frequented by the French marine. A series of cases that subsequently came under his care is related, with remarks as to diagnosis. Dr. Dupuy advocates the installation of a laboratory on board the vessels trading in the yellow fever zone whereby an early diagnosis of the disease could be made and the only logical method of treatment—that by serum therapeusis—could be carried out. The treatment of his cases consisted in regularly bathing the patients, in giving them an efficient purgative at the onset, and in administering antiseptic medication to the intestinal canal by salol or benzo-naphthol. The work also contains several instructive clinical histories of cases.

The Roentgen Rays in Therapeutics and Diagnosis. By WILLIAM ALLEN PUSEY, M D, and EUGENE WILSON CALDWELL, B S. Demy 8vo, pp. 591, and 176 illustrations. London, Philadelphia, and New York: W. B Saunders and Co 1903. Price 21*s*

THIS book is one which is indispensable to the x ray worker. The first part of 215 pages deals with the apparatus and with the uses of the x rays for purposes of diagnosis and is written by Mr. Caldwell whose name is well known as the inventor of a very useful form of electrolytic interrupter. The second part is by Dr. W. A. Pusey, professor of dermatology in the University of Illinois, and deals with the therapeutic applications of the x rays. The book is rendered additionally valuable because it supplies summaries of the experiences of other writers and because of the copious references which are given to their writings on the subject of x-ray therapeutics.

The future of x-ray work is largely bound up with the development of apparatus for direct use with the current [illegible] of the street mains When things can be so arranged that the practitioner may at once procure the illumination of a fluorescent screen by the turning of a switch the examinations of patients with the x rays will at once acquire a much more extended sphere of usefulness. Development along these lines is now progressing rapidly. Upon direct current circuits a simple arrangement of coil and turbine interrupter in a cabinet or hanging cupboard provides an outfit which can be worked with the minimum of attention and does away with most of the troublesome details of x-ray management. Almost equally good results can now be had upon alternating current circuits by means of a synchronous interrupter of the types designed by Dr. Batten and by Messrs. Siemens or by the use of an electrolytic rectifier with aluminium poles or by the new transformer of Koch. These instruments are worthy of more attention than they receive in the volume under review. For alternating circuits Mr. Caldwell advises the Gaiffe Galliot form of Wehnelt interrupter but this, in common with other forms of electrolytic interrupter, labours under the disadvantages of being noisy in action, of throwing a severe strain upon the tubes employed, and of being hardly suitable for prolonged use, such as may be needed in hospital practice, when the gradual heating of the fluid in the interrupter vessel becomes serious. We are still in need of an interrupter which will operate satisfactorily for two or three hours at a time The difficulty, it is true, may be partly overcome by the use of very large tanks of liquid. Capacities of five or six gallons have been found necessary by some operators in this country when working with electrolytic interrupters to delay this overheating effect. The use of the fluorescent screen for stereoscopic work is also described rather too briefly. This method of x-ray examination is still in its infancy but is likely to develop in time

In the second part the question of the therapeutic application of the x rays is ably handled in 17 chapters and of these five are devoted to the subject of malignant disease. Upon this important section of x-ray work a vast amount of interest is now concentrated. It appears certain that some real successes have already been obtained in the treatment of carcinoma and of sarcoma and the next few years will probably determine the value and the limitations of the benefit to be obtained from this method of treatment Rodent ulcer may be considered to be curable by x-ray treatment whenever its situation is such as to permit of the exposure of the diseased part to the rays. Details of the x-ray treatment of lupus and other forms of tuberculous disease and of various chronic skin affections are also considered and are dealt with in an impartial manner which will commend itself to the reader.

Photothérapie et
Light.) By
17 figures. 1
Price 4 francs

Professor Finsen in a preface to this book writes that the reader will find in its pages the best account of the subject and he draws special attention to its last chapter which, he says, provides a necessary counterpoise to the exaggerations and fantastic applications to which, to his great regret, photo-therapy has given rise. The chapter in question deals with the electric-light bath as a mode of general treatment, complains of the charlatanism which surrounds it, and points out that, although in a general way its action may be useful as a Turkish bath method, before any further utility can be conceded to it there is need for much patient laboratory work. This so called phototherapy is now very much in evidence in this country mainly through the medium of advertisements and is a popular quack remedy for almost everything.

The volume under review is a scientific study of the [illegible] biological effects of light and as such is a valuable contribution to the literature of the subject. The various lamp instruments used in phototherapy proper are described and figured. The iron electrode arc lamps of Bang and of Broca and Chatin are considered but no description is given of the condenser lamp with iron electrodes which is known in this country as the St. Bartholomew's lamp or Leslie Miller lamp. This instrument emits a light which is remarkably rich in violet and ultra-violet rays and is capable of giving very good results in the treatment of lupus.

Lectures on Physiology, published under the Authority of the University of London. Vol. I. Eight Lectures on the Signs of Life from their Electrical Aspect. By AUGUSTUS D. WALLER, M.D. Aberd., F.R.S. London: John Murray. 1904. Price 7*s.* 6*d.*

"The Signs of Life from their Electrical Aspect" is in many ways a very interesting volume. Considered in the first place as a sign of educational life on the part of the University of London it forms, it may be hoped, a prelude to a great advance. A book for which its author claims with truth the nascent state of its subject matter as an advantage is truly an omen of an alteration in character in the centre of English scientific pedagogy, and the University of London has wisely accorded its imprimatur to a work in which is displayed the living nature of the teaching now to be obtained beneath its roof. From it we learn that experimental tests are evidently applied before the students to the ideas which wit and experience and the continuity of knowledge produce within the mind of an investigator of eminence and distinction, and the resultant confirmation or rejection of such ideas is obviously watched with interest by the student in a lecture room surrounded by research laboratories where patient work may drive home every point. To be shown how to confront the fancies which skirmish beyond the margin of knowledge, to criticise the tendency of the facts afterwards elicited and the manner in which they are arranged by the skilled critic and worker authorised to teach them, is indeed to draw nutriment from an *alma mater* stimulated to continuous benevolence.

Dr. Waller has been for many years consistent in his belief that the electrical states and changes, which can be measured in animal and plant tissues, are of importance. He has been singularly successful in an endeavour to rescue the instrument by which they can be recorded and most sensitively measured from the sacred precincts of the dark room and its mysteries. His methods of using the galvanometer, and his manner of explaining its use, have brought it within the reach of students hitherto dismayed by the appalling ritual demanded, so they were led to think, by its devotees. A complete justification of this welcome attitude is to be found in the many phenomena which Dr. Waller has observed in apparently simple fashion. The "blaze currents" which form the subject matter of this book, and the text of the lectures recorded in it, are by no means the least interesting examples of this. Led to their study by an investigation of the currents obtainable from the eyeball, Dr. Waller has elicited a series of facts of considerable physiological interest and of probable technical importance in the future. The facts are not deposited vaguely in the arena of scientific knowledge but are carefully defined—that is to say, the positions in which they are developed and their relation to various changes in environment have been accurately determined by ingenious experiments. It seems probable, as in all similar work, that the phenomena may not finally bear the precise significance which is here attached to them and that many of the ideas which are made to hover so gracefully around them may subsequently prove evanescent. Dr. Waller is, however, himself quite clear upon this point, and part of the excellence of the work is that a clear boundary is placed between fact and fancy.

The book, in fact, like all the volumes which Dr. Waller has produced for the benefit of the student, is of great educational value and is none the less so in this case because the reader is designedly never allowed to escape from the personal magnetism of his teacher.

The Pathogenic Microbes. By M. le Dr. P. JOUSSET, Physician to the Hospital Saint-Jacques, Director of the Laboratory of Bacteriology of the Hospital Saint-Jacques. Authorised translation of HORACE P. HOLMES, M.D. Philadelphia: Bœrecke and Tafel. 1903. Pp. 192. Price $1.00.

So far as can be perceived through the somewhat turbid medium of the translation this short work of Dr. Jousset seems to be an interesting essay on the bearings of the general principles of bacteriology on clinical medicine. It appears to be modelled on the work published by Professor Bouchard in 1892 and it is implied in the preface that the present book is concerned chiefly with the discoveries of the last ten years and brings Professor Bouchard's book up to date. There is no indication that it recognises any discoveries which have not appeared in French literature. The work does not describe the pathogenic microbes, as might be suggested by the title; individual micro-organisms are only mentioned when they serve to illustrate some general principle, such as variation of virulence or latency. The author strongly and rightly insists that the microbe, though indispensable, is only one of the factors necessary to the production of a bacterial disease and draws attention to the great importance of the conditions found in the body of the host to which the microbe gains access. Unfortunately, these conditions are disguised under the expressions "morbid spontaneity" and "morbid imminence," terms which we venture to think will convey little meaning to the English reader. In the chapter on Bactericidal Sera the author propounds what we believe to be an original view as to the relation between *alexin* and *sensitising body*—viz., that the former is transformed into the latter by heating to 55° C. (p. 57). The view that the action of antitoxin (a term much disliked by the author) on toxin is not of the nature of a chemical neutralisation is strongly asserted but none of the experiments which traverse this position are even mentioned. We regret to see Haffkine's cholera "vaccine" once more spoken of as a cholera "serum." It has already been suggested that the translation is unsatisfactory. It is little more than a literal transcript and it is difficult to do justice to the matter when presented in this form. Whether a well-known organism should be spoken of as the "bacillus coli" or the "bacillum coli" appears to depend on "the taste and fancy of the speller," as both forms may be met with even on the same page.

As usual in French books there is no index. We may point out that in the few footnotes to which the initials of the translator are attached there is no evidence of the eccentricities of style which disfigure the body of the translation.

LIBRARY TABLE.

Medical Annals and Report of the Hamidié Children's Hospital for 1902. Fourth year of publication. Constantinople. 1903. Pp. 663.—This report of what is apparently a first-class hospital organised upon the most modern lines contains some very interesting matter. Although the Hamidié hospital was founded by the Sultan for women and children yet a number of wounded soldiers were treated there during the 12 months October, 1902, to October, 1903. The report is printed mainly in Turkish but there are also articles in French, German and English, together with records from the *livre d'or* or visitors' book. Most of the English articles in the book are quite correctly printed but the following is worthy of reproduction as a fearful example of what may occur from what is said to be a common failing of the medical profession—namely, the inability to write legibly:—

> It has given me the greatest pleasure to have been turn round the hospital and I am greatly stuck with the manner in which the work is carried on, and also with all the haket objects and instruments that are used.
>
> ——, M B E N.,
> Blackleen,
> Lancardiv, England.

We have omitted the practitioner's name, but we have left in the letters which we presume refer to a qualification. Among the preliminary articles is one by M. Barcilles, the secretary and librarian of the hospital, upon medical science among the followers of Islam. This is an interesting historical retrospect of "Arab" medicine. We learn from M. Barcilles that the treatment of fractures by immobilisation was in vogue in Constantinople towards the end of the 17th century. Fractures were then put up in plaster-of-Paris splints and if the fracture was compound the splint had windows cut in it. This we fancy was long before the introduction of the plaster splint into Western Europe.

The Book of Herbs. By Lady Rosalind Northcote. London: John Lane. 1903. Pp. 212 Price 2*s.* 6*d.* net.—Lady Rosalind Northcote has collected in her little book a vast amount of information about herbs. She confesses that her definition of what constitutes a herb is somewhat indefinite and we see that she includes such plants as cardoons, rhubarb, samphire, skirrets, and chives. However, anybody who has a garden will do well to get this book and to grow herbs according to the directions given therein. The latter portion of the volume is taken up with an account of the uses of herbs in medicine and in magic, and with sundry details of the folk lore of herbs. With all the absurdities with which the use of herbs and other plants in medicine was overlaid there was often a substratum of truth. For instance, not so very long ago it was the custom in the West of England to rub the inside of a churn with nettles to keep it sweet, and cream cheeses were laid upon nettles to prevent them going mouldy. Nowadays the very latest disinfectant and antiseptic is formaldehyde and yet it has always existed in nettles together with formic acid.

Charles White, F.R.S.: a Great Provincial Surgeon and Obstetrician of the Eighteenth Century. By Charles J. Cullingworth, M.D. London: Henry J. Glaisher. 1904. Pp. 56. Price 2*s.* 6*d.*—Biographies of medical worthies who have played important parts seldom fail to be interesting and these conditions are fully realised in the present volume which is a publication in book form of an address delivered by Dr. Cullingworth before the Medical Society of Manchester on Oct. 7th, 1903. A lengthy abstract of the address appeared in The Lancet of Oct. 17th, p. 1071. Charles White was one of the founders of the Manchester Royal Infirmary, the origin of which dates from 1752, and he was an active member of the staff until 1790. The illustrations comprise a portrait of Charles White, a view of his house in King-street, and two views of the Infirmary. It would, perhaps, have been better if the names of these views had appeared on some part of the plate itself instead of on a separate and unpaged leaf.

Traité de Radiologie Médicale. Published under the direction of Ch. Bouchard, Professor of General Pathology to the Faculty of Medicine, by MM. Béclère, Bergonié, Bertin-Sans, Bordier, Bouchacourt, André Broca, Cluzet, Fabre, Guilloz, Imbert, Leduc, Le Noir, Marie, Mignon, Maunoury, Oudin, Ribaut, Ruault, Sagnac, Scheier, Villard, and Weiss. With 357 figures and seven plates. Paris: G. Steinheil. 1904. Crown quarto, pp. 1100. Price 30 francs.—This important work covers the whole ground of radiography and its applications to medicine and surgery. It is edited by Professor Bouchard with the collaboration of a large number of distinguished writers. The consideration of the Crookes tube and of the various electrical generators employed for the production of the x rays, together with a study of the physics of the x rays, occupies the first part of the volume The second part deals mainly with radiography in all its medical applications. Every detail of technique for the operations of x-ray work for purposes of diagnosis finds its proper place in these pages. X-ray therapeutics are somewhat meagrely dealt with in the concluding chapter and the dangers and accidents of x-ray work are considered at somewhat greater length in the preceding one. As a work of reference this volume is very valuable and its magnitude serves to illustrate the enormous developments of x-ray work up to the present time.

Cours de Dermatologie Exotique. (*A Course of Lectures on Tropical Diseases of the Skin.*) Par E. Jeanselme, Professeur agrégé à la Faculté de Médecine de Paris, Médecin des Hôpitaux; recueilli et rédigé par M. Trémoilières, Interne des Hôpitaux. Avec 5 cartes et 108 figures dans le texte en noir et en couleurs. Paris: Masson et Cie. 1904. Pp. 403. Price 10 francs.—Professor Jeanselme was appointed to lecture at the Institut de Médecine Coloniale de Paris on the diseases of the skin peculiar to, or especially prevalent in, the tropical regions and in performance of that duty he delivered the lectures which were reported by M. Trémoilières. We consider that the author has done well to publish these lectures, for they deal with a branch of dermatology not sufficiently studied until very recently. In this country the two schools of tropical medicine are doing much to remove from us the reproach of neglecting the diseases of warm climates though so many parts of the British Empire lie between the tropics. The diseases dealt with in this volume comprise leprosy, syphilis, yaws, and verruga Peruana; the Oriental sores, various hyphomycetic conditions such as tinea imbricata, elephantiasis Arabum and other conditions connected with animal parasites, and a few other diseases which are difficult to classify as we know but little of their mode of origin. The style in which the book is written is fluent and pleasant to read and this work should prove an interesting introduction to tropical dermatology for any medical man proceeding to a warm climate. It is excellently illustrated.

Nurse Charlotte. By L. T. Meade. London: John Long. 1904. Pp 319.—Like many of Mrs. L. T. Meade's writings, this book will serve to amuse medical readers without affording instruction beyond the indication of the many pitfalls besetting the path of those who deal with medical matters with insufficient equipment. On the eighth page a young lady announces her intention of getting "a post at St. Thomas'" through the influence of a country practitioner. She succeeds, but we find her installed at St. Christopher's where medical and surgical cases are strangely mixed up, where the leading physician is obviously engaged in general practice and has long had his eye on the country practitioner "as a possible partner" for himself. The description of the inner life of the nursing staff is nearer the truth than was the pitiful caricature of hospital nursing once depicted by Mr. Hall Caine, but that is all the commendation which we can give honestly. We doubt also if any nurses genuinely engaged in nursing will find the story wholly flattering to the system or to the individuals concerned, although the heroine is meant to be an angel of light.

JOURNALS AND MAGAZINES.

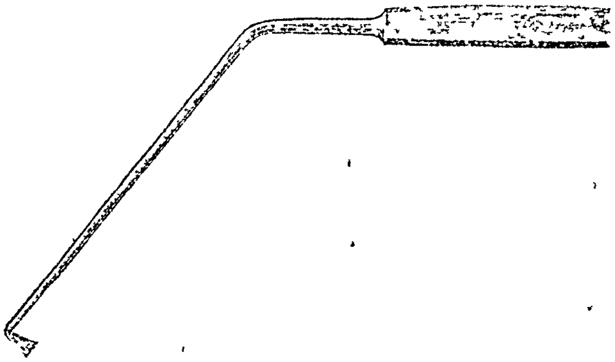
The Journal of Physiology. Edited by Sir Michael Foster, K.C.B., F.R.S., and J. N. Langley, F.R.S. Vol. XXX., Nos. 5 and 6. London: C. J. Clay and Sons, Feb. 25th, 1904. Price 8*s.*—The contents of this issue are as follows: 1. J. A. Macwilliam, M.D., Professor of Physiology, with A. H. Mackie, M.D., and Charles Murray, M.D., Assistants in Physiology in the University of Aberdeen, on the Intravascular Injection of Salts and of Nucleo-proteid, with 14 figures in the text. Tracings are given showing the effect of the intravascular injection of various sodium salts on the respiration. The exophthalmos which has long been known to follow the injection of nucleo-proteid obtained from the thymus or from lymph glands is shown in this article to be due to blood clots at the back of the orbits. 2. Otto May, M.D., on the Relationship of Blood-supply to Secretion with especial Reference to the Pancreas, with nine figures in the text. Dr. May finds that there is no direct relationship between the rate of secretion of pancreatic juice and the amount of its blood supply. Secretion continues for some time after complete cessation of the pancreatic secretion. He also finds that the pancreas is well supplied with vaso constrictor nerves which in the cat proceed from the solar plexus in the bundle of post-ganglionic fibres accompanying the cœliac axis artery. 3 W. M. Fletcher, the Osmotic Properties of Muscle and their Modifications in Fatigue and Rigor, with 11 figures in the text. 4. J. N. Langley, F.R.S, and H. K. Anderson, on the Union of the Fifth Cervical Nerve with the Superior Cervical Ganglion. The experiments of the authors of this article lead them to conclude that certain somatic fibres are capable in favourable circumstances of making functional connexion with sympathetic nerve-cells. 5. Keith Lucas, on the Influence of Tension upon the Contraction of Skeletal Muscle at High Temperatures, with five figures in the text. 6. E. G. Wilcock, the Action of the Rays from Radium upon some Simple Forms of Animal Life. 7. Major R. H. Elliot, M.B, and E. Burnett, B A, a Modification of Professor Schäfer's Frog-heart Plethysmograph, with some observations on the mode of using it, with one figure in the text. 8 R Row, M.D., on Some Effects of the Constituents of Ringer's Circulating Fluid on the Plain Muscle of Rana Tigrina, with 15 figures in the text. 9. T. G. Brodie, M.D., and W. E. Dixon, M.D., Contributions to the Physiology of the Lungs, with 10 figures in the text. This article is occupied with the consideration of the vaso motor nerves of the lung. The authors give the results of their experiments with various drugs on the rate of flow of blood through the pulmonary vessels. They find the pulmonary arterioles have no vaso-motor nerve supply. 10. W. B. Warrington, M.D., Note on the Ultimate Fate of Ventral Cornual Cells after Section of a number of Posterior Roots. This issue of the journal contains the Proceedings of the Physiological Society on Dec. 12th, 1903, and Jan. 23rd, 1904.

The Journal of Hygiene. Vol. IV., No. 1. January, 1904 London: C. J. Clay and Sons. Price 7*s.* net.—This number opens with a joint paper on the Chemical Constitution of the Tubercle Bacillus by Dr. William Bulloch and Dr. J. J. R Macleod, who arrive at the conclusion that the acid- and alcohol-fastness of the tubercle bacillus is due to the presence of an alcohol. Dr. Alexander Edington makes some further remarks on the production of a malarial form of South African horse-sickness, and Dr. E F. Bashford treats of some fundamental experiments in immunity in a paper which is accompanied by some very instructive plates. Dr. A. E. Boycott and Dr. J. S. Haldane contribute their second paper on Ankylostomiasis in which they discuss the methods of diffusion and the means of diagnosis and treatment of the disease. In the last article Dr. Herbert E. Durham passes in review the several theories which have been held responsible for beri-beri and he arrives at the conclusion that "the appearances and disappearances of beri-beri and the more or less seasonal waves of the disease are not unlike those which are seen in the case of the infective diseases which are met with in this country." Dr. Durham, in fact, thinks that beri-beri may prove to be a communicable disease and that it has to be considered rather in the light of what he calls a "gang" or "institutional" disease than as a "place" or "house" disease.

New Inventions.

INSTRUMENT FOR THE REMOVAL OF FOREIGN BODIES FROM THE NOSE.

THE accompanying illustration represents a little instrument which I have designed for the removal of foreign bodies from the nose. The ordinary methods of removal are not always satisfactory and it was after meeting with a difficult case in which an indiarubber teat had been introduced into one of the cavities that I sought for some new instrument likely to prove valuable in such circumstances. As will be seen, the end of the instrument is flattened and turned down, this portion being six millimetres in depth and being provided with three small teeth. It can be readily passed into the nose beyond the object to be withdrawn and gentle traction will lead to rapid removal of the foreign body without laceration of the surrounding parts. Rhinoliths may, no doubt, be dealt with in the same way. Messrs. Mayer and Meltzer, of 71, Great Portland-street, London, W., made the instrument for me.



ARTHUR ROBERTS, F.R C.S. Edin.,
Surgeon to the Ear, Throat, and Nose Department,
Reading. Royal Berkshire Hospital.

NOTE ON A SIMPLE STERILISABLE BAG FOR CLOSED ETHER INHALERS.

THE indiarubber bags for Clover's and other ether inhalers are liable to perish unless often used and kept in a warm place, besides not always being easily replaced. Moreover, they will not usually stand repeated or prolonged boiling. I should like to describe a simple home-made article made from jaconet, or still better, from a new waterproof material which can be boiled called "mosetig battist." This is sold in widths of 36 inches and one yard is enough to make four Clover's bags. There are other materials of like make sold —e.g., one called "billroth." The directions for making the bag are as follows. A yard of battist is taken and doubled so that the shiny surface is inside, then the pattern is laid on the battist (using no pins), the bag is cut out, then stitched round its edge, leaving a margin of from one-eighth to one-quarter of an inch, and, still keeping the shiny surfaces together, is turned inside out and stitched round again, making a flat seam. Then the bag is inverted and is ready for use. The shiny surfaces seem to adhere along the seam. Bags so made are airtight and watertight and can be used just like rubber ones, than which they are very much cheaper. The neck, of course, should be made wider than that of a Clover's bag as it will not stretch. A rubber band or piece of string is used to fix the neck to the angle piece of the inhaler. These bags, t[illegible] quickly and easily made at home, are very chea[illegible]g, and are very lasting.

Birmingham. [illegible]

THE LANCET.

LONDON: SATURDAY, APRIL 9, 1904.

The Education Act and Physical Fitness.

THERE are indications that in a physical sense the people of this country are passing through a critical stage. We do not go so far as to suggest that upon the nature of the steps which are taken now to improve the condition of the individual, and thereby of the mass, may depend the future survival of the nation as a leading commercial and fighting entity. We know that much of the talk about national physical deterioration is only talk, but none the less there is an uncomfortable substratum of truth at the bottom of this talk. The position is a serious one and it behoves every Englishman worthy of the name to do his part in bringing about a better condition of affairs. It is impossible at present to demonstrate by statistics which shall be beyond criticism the alleged physical deterioration of the people. As yet no serious study of anthropometrics has been undertaken and there are consequently no data available which will allow us to compare the physical condition of our predecessors with that of the present generation. Doubtless the necessity for the compilation of accurate data in the above sense will form one of the recommendations of the Select Committee on Physical Deterioration which is now sitting. The fact that the death-rate is diminishing and that the average duration of life is increasing cannot be regarded as negativing a view that the physical condition of the people is deteriorating. By tending plants in greenhouses during the winter months we can reduce their death-rate almost to *nil* but it would be altogether erroneous from this to assume that the plants were more hardy. That the physical condition or fitness of those who spend their lives under rural conditions is *ceteris paribus* better than that of those who pass their lives in the din and dirt of our large cities must, it seems to us, be accepted as a fact, and if this be conceded the rapidly increasing tendency to forsake the country for the town must be making for deterioration rather than for improvement. Sedentary lives, overwork, smoke, noise, and absence of fresh air and light are all forces which on general biological lines are likely to lead to diminished vitality and the problem of the future is how best to counteract these detrimental agencies.

In our view a powerful instrument in this direction is at hand in the new Education Act. The education of the children of this country has until quite recently been in the hands of authorities who have had no interest in, and no concern with, the public health and who were not elected to safeguard the health of the nation. This state of affairs still obtains in the metropolis. But after May 1st the education of the whole country will in large measure be entrusted to authorities who have for many years been concerned, at least in some degree, with the public health and who will now have to deal, in addition, with public education. It is the primary duty of the education authority to teach the children something by which they may obtain the means to live; it is one of the duties of the sanitary authorities, although they have largely neglected it in the past, to teach the people *how* to live. It is therefore reasonable to hope that the sanitary authorities will not, in discharging their educational functions, lose sight of the functions for which they were established. There is now before the county boroughs, and to some extent before the district councils of this country, an opportunity for work in a national and imperial sense which has never before been equalled in their histories. They have now an opportunity of eclipsing in a public health sense all previous records. It is to be hoped, therefore, that the new education authorities will have brought home to them the urgent necessity for detailed attention to the physical welfare of the children. We should like to see their attention called to the subject by the central health authority, the Local Government Board, a department which might very well take upon itself a little initiation in this all important matter. The expiring London School Board has done a good work in investigating into, and caring for, the health of its charges, as anyone who has read Dr. J. KERR'S first and last report will appreciate; but it is disappointing to find that as regards any scientific investigation into the ventilation, heating, and lighting of the schools very little has been attempted and it seems to us that in the past far too much attention relatively has been devoted to infectious diseases alone. The mortality from, and sequelæ of, infectious diseases form but a small factor in the national health. The first step should, in our opinion, consist in the appointment of medical officers who should, so far as is possible, be in possession of special experience. In some cases use might be made of the medical officer of health and by combining this appointment with his other duties it would be possible to appoint whole time officers to a greater extent than is the case at present. Before any child is allowed to attend school such child should be provided with a medical certificate, given after careful examination, testifying to his or her mental and physical fitness to undertake the work, and there would, we think, be no objection to the postponement of the commencement of education to a somewhat later age than at present. With this certificate should be furnished particulars as to the weight, height, and age of the child and the condition of his or her special senses. Such information should be brought up to date at least once annually, when the teeth and the special senses should be re-examined. When such data have been collected for some years we shall no longer find as we find in Dr. KERR'S annual report a statement of regret that "we have no trustworthy measurements of the development of London children."

But in addition to this record of the physical progress of the children it is essential that the rudiments of healthy existence shall be impressed upon them. The value of cleanliness, of fresh air, and of light in the prevention and reduction of disease should be taught by the aid of simple diagrams and illustrations and the children should be made to feel the effects of physical fitness by carefully arranged exercises carried out in the open air. In a word, the rising generation should be taught the vast importance of vigorous health in the struggle of life and the best means by which it may be attained and kept. The children should have the love of fresh air, cleanliness, and light so ingrained into them that when they grow up they will refuse to inhabit the slums and will bestow administrative power not upon the jerry builder but upon the representative who will do most for the health of the people. In the girls' schools, too, the elements of cooking should be taught and the older children should learn from experienced teachers how to purchase food which will provide the highest nutritive value for any given outlay. It is in ways such as these that we shall gradually develop a health conscience which will react upon the physical condition of the future generation. The Local Government Board should call the attention of all medical officers of health to the desirability of dealing with this subject of physical education in their annual reports and copies of such reports should be sent to the members of the local educational committees. The Local Government Board owes, we think, this initiative step to the nation and it may well be asked :—If the physical condition of the people does not concern that department upon which department does the duty devolve? We are glad to see that in some instances medical officers have already been appointed and that in other cases, of which Richmond in Surrey is an example, such an appointment has been recommended by the medical officer of health.

◆

The Cumulative Action of Drugs.

IN several recent prosecutions for the sale of impure drugs it has been interesting to note that in the course of the evidence reference has been made to the evil "cumulative" effect of the trace of impurity. This has been mentioned especially in connexion with cream of tartar in three samples of which lead was found in the proportion of three-quarters of a grain to the pound, while a fourth sample contained one-tenth of a grain of arsenic to the pound. Of course, these contaminations ought not to be present and in three of these cases penalties were inflicted. In the fourth case the druggist was able to show that the article was sold as received with a warranty from a wholesale house and, since it was necessary that proceedings against the warrantors should be taken within six months of the time of the giving of the warranty, both the retail druggist and the wholesale house escaped the infliction of a fine. In these cases and in many others the analyst has given evidence that in his opinion the contamination was prejudicial to the health of the consumer and the question of cumulative action has been raised to support this opinion. Without disputing the validity of this claim and without defending or excusing the presence of these impurities it may be of interest to review briefly the present state of our knowledge of the mode of action of cumulative poisons or drugs. It has long been recognised that occasionally undesired effects result from the administration of remedies which have been given in average or moderate doses and when such accidents occur it has been customary to refer them either to some special idiosyncrasy or to cumulative action. The former explanation is the easier way out of the difficulty since it assumes a peculiar individual intolerance of drugs which are generally beneficial or at least harmless in moderate doses and it thus shifts responsibility from the prescriber to the consumer who, presumably, if already aware of individual intolerance, should have given the word of warning which would have prevented a repetition of unpleasant experiences. Special idiosyncrasy can only be ascertained by experiment but there is no need to repeat the experiment if the disquieting result can be predicted with accuracy, even though the explanation of the result still evades scientific precision.

On the other hand, the possession of cumulative action appears to be a special attribute belonging to the drug rather than to the consumer. While intolerance applies to some unknown individual peculiarity for particular drugs cumulative action seems to depend upon some disproportion between the rate of absorption and the rate of elimination and it is a property which in all likelihood affects most individuals in a precisely similar fashion. Cumulative action, therefore, is to be explained from the known physiological effects of the drug and it can, within certain limits, be determined by experiment upon animals and thus guarded against in practice. The best known illustration of cumulative action is afforded by digitalis and it has been ascertained that the occasional disproportionate effect in retarding the cardiac pulsations occurs when its elimination by the kidney, that is the diuretic action, has been checked. This is not the sole explanation, however, since it would appear that in some cases active principles may pass out of the blood-vessels into effusions into serous cavities, or into subcutaneous tissues and that they may there be innocuous but again become potent after reabsorption. It is an aphorism of medicine that a drug is active so long as it is circulating in the blood. On this hypothesis the amount in circulation at any given time must depend upon the degree of solubility and upon the rate of elimination through any excretory organs. Circumstances favouring solubility must increase the rate of absorption and in this we find the explanation of the variations in the results which may ensue from the different modes of administration of sparingly soluble drugs such as sulphonal. The rate of elimination is more difficult to control and it is often more difficult to explain. It may depend upon the nature of the active principle of the drug; thus while glucosides are slowly absorbed they are much more slowly eliminated and thus they may produce an overwhelming influence after long-continued use with little apparent effect. Dr. HOBART AMORY HARE has recorded an example of cumulative action with digitalis in a case of pleuritic effusion in which the toxic influence persisted three days after the cessation of administration and he also mentions another instructive case in which the relief of ascites by tapping was followed by reabsorption of fluid from the subcutaneous tissues and by a violent explosion of digitalis poisoning.

With regard to mineral substances the term cumulative action has been less commonly employed, perhaps because the effects produced have been less violent, less obvious, and less immediately consecutive to the use of the drug. There can be no doubt, however, that many minerals are slowly eliminated and that they are largely deposited in various tissues in which they may produce deleterious effects. The results of the continued absorption of small quantities of arsenic have been emphasised since attention was directed to the subject in connexion with the contamination of beer with this substance. Antimony, mercury, and lead also afford examples of mineral drugs which may similarly produce toxic symptoms of long duration. Some symptoms of bromism and iodism, however, probably result from direct irritation during elimination and thus do not afford examples of cumulative action.

The importance of due appreciation of the relative rates of absorption and elimination is not limited to the occasional presence of impurities from which we should be protected by examination of the drugs employed. This knowledge should also govern the dosage and administration of drugs which have the undesirable property of accumulating within the system, and it affords another opportunity of laying stress upon the risks which may arise from the possession of prescriptions given without sufficient warnings of the limits of safety or the need of caution. Prosecutions for impurities and adulterations are interesting and necessary but they would fail in their full measure of instruction if they did not serve also to direct attention to possible dangers which may arise during the injudicious use of some most trusted remedies.

◆

Remarkable Resuscitations.

The fear of being "buried alive" seems to be inherent in the minds of certain individuals and elaborate instructions are occasionally included in their last testaments in order to prevent a fearful calamity, the occurrence of which is not denied though its frequency has been much exaggerated by popular report. The uncertainty of the signs of death must be acknowledged but medical literature contains only one or two authenticated cases of a living person having actually been buried. The first man of science or philosopher whose opinion is available as to what constitutes a proof of death is Democritus and he maintained that there was no certain sign of the cessation of life. Celsus severely criticised this opinion and asserted that if the apparent identity of certain signs deceives an unskilful physician an experienced and intelligent man cannot be mistaken. Orfila, Fodéré, and Michel Levy all believed in the possibility of premature burial. Lancisi and Louis, on the other hand, controverted such a doctrine. Brouardel,[1] in his interesting work "Death and Sudden Death," which has been translated into English by Dr. F. L. Benham, whilst admitting that premature burial cannot be absolutely denied, demonstrates that it must be extremely rare. In support of this contention he instances the mortuary chambers established in Germany and elsewhere in which dead bodies are placed, a bell rope being attached to the hand of each. He says "that from the time that mortuary chambers were instituted—and that at Weimar dates from 1792—neither at Weimar nor at Munich ...... nor anywhere else, I believe, has anybody ever rung that bell."

Although, then, premature burial for all practical purposes may be considered not to take place, nevertheless many instances are on record in which by skilful treatment the apparently dead have been restored to life. The majority of such cases have occurred in individuals who have been removed from the water apparently lifeless. It is difficult to fix accurately the time in which drowning proves fatal. In human beings, as a rule, asphyxia supervenes in from one minute to two minutes after submersion and death usually before the expiration of five or six minutes, but life may be considerably prolonged if from any cause water has been prevented from entering the lungs. A case was recorded in The Lancet by Mr. Charles Pope[2] in 1881 in which a man was sailing in a boat when it capsized and he fell into the water with some weights on top of him, so that with the exception of his left arm he was entirely and continuously submerged for from 12 to 15 minutes. He was resuscitated with considerable difficulty and eventually recovered. The weights probably prevented water from entering the lungs. Longer periods of submersion with recovery than this, however, have been recorded. In one case submersion had lasted for 20 minutes,[3] and in another, which is, however, "doubtful," one hour is the recorded time.[4] Examples again have been recorded of resuscitation after two hours' employment of Silvester's method of artificial respiration, the subjects being apparently dead.[5] On one occasion[6] a boatman towed the body of a man ashore and pronounced life to be extinct; a medical man corroborated this opinion but two more sanguine bystanders began vigorous treatment, with the result that the apparently drowned man entirely recovered from the effects of the submersion. Another class of case in which resuscitation has occurred, although the individual was apparently dead, is after hanging. Hofmann reports such a case.[7] A criminal, who was sentenced to be hanged, had round his neck enlarged glands which partly neutralised the constriction of the encircling slip-knot. The body remained suspended for 20 minutes and death was certified to have taken place. The body was then transported in a van at a rapid pace to the post-mortem room. There was some distance to go and when the van arrived the physicians were greatly surprised to see instead of a corpse an individual who raised himself up before them and looked at them with a scared expression. Three or four hours afterwards the man died from pulmonary congestion, evidently a result of the hanging. Other criminals are believed to have been luckier, for there are stories, which seem to have their origin in fact, of the recovery and escape of men who have been judicially hanged.

It is not a matter for wonder that in cases of concussion of the brain mistakes have arisen. During the retreat from Russia General Ornano had his head grazed by a bullet while in the act of charging the enemy; he fell from his horse and his orderly ran to his assistance but found that he showed no signs of life; he therefore buried him under a heap of snow. The orderly then went to announce the death to Napoleon. Two hours afterwards General Ornano appeared and reported himself to the EMPEROR; he lived a long time afterwards and was actually one of the pall-bearers to the orderly who had buried him. The after-effects of lightning have given rise to similar error. SESTIER, in his work entitled, "De la Foudre," relates seven cases in which apparent death lasted for five or six hours. BROUARDEL records the case of a boy, aged 13 years, who fell from the sixth storey of a house on to the pavement. The boy had been taken to a druggist who had pronounced him to be dead and sent him on to a hospital where admission was refused as he was supposed to be dead. BROUARDEL, however, saw him and stated that the lad was alive, although the sounds of the heart could not be heard on auscultation. The boy received suitable treatment and recovered.

[6] [illegible]

Alcohol may produce a condition of apparent death. A case is recorded of an old woman who was found in the street and in whom no sign of life was apparent. She was conveyed to the hospital and the rectal temperature was found to be 77° F. Energetic treatment was resorted to and she recovered. Prolonged narcotism brought about by other substances sometimes gives rise to natural alarm. The late Sir BENJAMIN WARD RICHARDSON[8] mentioned the case of a medical man who took 120 grains of chloral. When seen he was to all common observation dead, there was no sound of respiration, it was very difficult to detect the sounds of the heart, there was no pulse at the wrist, and the temperature was 97° F. He had been in that condition for some hours. He was revived by raising the temperature of the room to 84° F. and injecting warm milk-and-water into the stomach. He made a perfect recovery. Finally, we may refer to a class of case more or less familiar to all members of the profession—namely, apparently stillborn infants who if left simply to the care of the mother or to an ignorant midwife surely perish but if properly attended to in all probability survive. DEPAUL succeeded in restoring newly born children by means of pulmonary insufflation one and a half, two, and even three hours after the heart had ceased to beat.

The instances that we have recorded of resuscitation of the apparently dead are, of course, of extremely rare occurrence In the vast majority of instances no difficulty is experienced by a medical practitioner in determining whether or not death has taken place but occasionally cases are met with in which some doubt may exist and it is needless to add that in such circumstances no efforts to restore animation should be relaxed until it is absolutely determined that all vital processes are extinct.

Annotations.

"Ne quid nimis."

THE NOMENCLATURE OF DEATH CERTIFICATION.

The Registrar-General has just caused to be distributed copies of the new list of diseases causing death which is now in use in the General Register Office at Somerset House as well as in the similar offices of Scotland and Ireland The list is based on the "Nomenclature of Diseases" authorised by the Royal College of Physicians of London. In the notes which accompany it a hope is expressed that in future medical practitioners will assist the work of registration and the compilation of statistics by abandoning so far as practicable sundry terms now deemed obsolete, such as "convulsions," "scrofula," and "phlegmon," which are given in the list, to say nothing of such vague words as "consumption" or "decline," which belong only to the popular terminology. Certain suggestions which give evidence of a commendable desire to establish the statistical tables upon a foundation of scientific pathology are offered, as thus: "In certifying deaths from small-pox the patient's condition with respect to vaccination should be carefully stated." Puerperal "fever" is to be described as pyæmia, septicæmia, or septic intoxication of puerperal origin. Three forms of pneumonia are recognised and are included under "general diseases." Malignant disease is to be differentiated into carcinoma or sarcoma when possible and care is to be taken to specify the particular organ or part affected. The epidemic form of cerebro-spinal meningitis is to be distinguished as cerebro-spinal fever; the exciting cause of "peritonitis" is to be mentioned and the nature of a "tumour" is to be explained. If any exception is to be taken to these and to the other propositions set forth it can only be on the ground of want of feasibility. It may not be possible always to state the cause of death with the wished-for accuracy. There is in private practice usually a difficulty in obtaining leave to make a post-mortem examination and without such examinations it is doubtful whether the objects of the new arrangement stand much chance of being realised. Nor is this the only direction in which obstacles are to be found. A covering letter to the medical officers of asylums asks that in certifying the deaths of persons of unsound mind "particulars of the definite brain disease for which the patient was under treatment in addition to any disease other than brain disease which may have been the immediate cause of death" shall be inserted in the certificate. In the present condition of cerebral pathology this is hardly practicable. Patients in asylums are rarely under treatment for "definite brain disease" in the pathological sense. The clinical aspects of their disorders form the basis of the classification of mental diseases. It is assumed with some show of reason that every mental abnormality is correlated with a structural change in the brain but the exact nature of the relation is yet obscure, for the alterations in the brain substance are not always visible and if visible may appear inconstant. Only, perhaps, in the case of general paralysis of the insane does the train of symptoms afford an index of the progression of the process of cerebral degeneration. One other point occurs to us. Alcoholism is mentioned as a cause of death but no allusion is made to it in the notes appended.

THE HOLMAN TESTIMONIAL.

FOR the last 50 years the name of Constantine Holman has been prominent in all the public work of the profession as treasurer and vice-president of the British Medical Association, vice-president of the British Medical Benevolent Fund, president of the Surrey Benevolent Medical Society, treasurer and vice-president of Epsom College (for which he has collected over £7000 by his personal efforts), and member of committee of the Royal Asylum of St. Anne's. He has rendered signal services to his profession and the cause of charity. So great have been these services that, as we have already announced, it is thought desirable by his friends and colleagues that some record of their appreciation should be established. It is proposed to devote the proceeds of this testimonial to the erection of an art and reading room at *Epsom College* to be called the "*Holman Art and Reading Room*." Subscriptions of any amount will be received by Dr. John H. Galton, Chunam, Sylvan-road, Norwood, S.E.

treasurer. Communications should be addressed to Mr. W. A. Berridge, Oakfield, Redhill, secretary.

SANITARY WORK.

THE Lord Mayor of Manchester took the chair on March 1st at the annual meeting of the Manchester and Salford Sanitary Association. The Bishop of Manchester (Dr. Knox) and the Bishop of Ripon (Dr. Boyd Carpenter) were present. The report showed that the association was still watchful and diligent in the cause of public health. The Bishop of Manchester said that at about the beginning of last century the idea was that people would see how uncomfortable it was to live in misery and degradation and so would put out their best efforts. This theory was found wanting and the great problem was—how much they must leave to individual enterprise, what was to be the share of benevolent enterprise, and what was the exact position of the State and municipal enterprise in dealing with the evils around us. The Bishop of Ripon was glad to see that Manchester was in earnest about the public health. He advocated authorised medical inspection in schools, the distribution of information, and especially the proper feeding of children. "The committee regretted the claims of the association for increased pecuniary support were not recognised adequately." Much more good could be done with a small addition to the funds. Donations to the amount of £100 are wanted to meet existing liabilities and additional annual subscriptions to the amount of £50 are needed. *Surely in a wealthy city like Manchester there should be no difficulty in raising these small sums.*

GUARDIANS AND THEIR OFFICERS.

CERTAIN boards of guardians are just now considerably perturbed by what are to them uncomfortable and unexpected results of modern democratic tendencies. At the meeting of the Birkenhead guardians on March 29th a member asked whether it was true that one of the board's paid officials had nominated a gentleman as a guardian at the recent election. The question proved to have only too sure a foundation on fact, for it appears that not one officer but two officers, and those district medical officers, had acted in the way described. Thereupon the board, metaphorically speaking, demanded the heads of the guilty parties. One member was "surprised that such a thing should be brought before them in these enlightened days" and wished to fly to the Local Government Board for vengeance. Another of less truculent disposition suggested that the officers "might have signed not knowing it was wrong," which seems likely enough. A third with profound sagacity feared that the matter might lead to "possibilities of which they had not the slightest idea" but was apparently unable or unwilling to be more explicit. It was eventually decided to let the matter drop, perhaps because there was nothing else to be done, in the hope that the offenders would be deterred in future from repeating their misdeeds by reflecting on the storm which they had raised. Another aspect of the same lamentable disregard of parochial sensibilities has been visible at Lambeth. At a meeting of the board for that district a lady guardian communicated the distressing intelligence that several superannuated Poor-law officers were standing as candidates at the elections shortly to be held. She asked whether this kind of thing could not be prevented; it could, she thought, never have been contemplated that such persons should be able to get elected and she, also, wanted to appeal to the Local Government Board. The clerk to the guardians said that that august body had been appealed to but declined to offer any opinion as to the merits of the case. However ill it may consort with the traditions of a parish that servants or former servants of a board should be enabled to control in some slight degree its policy there is really no cause for alarm in the development referred to. A district medical officer is none the worse fitted for attending to his duties because he exercises his rights of citizenship and to object to the election of some particular representative on the ground that he is enjoying the annuity which, through the agency of the Superannuation Act he has purchased for himself, is so eminently illogical that it is surprising that anyone could take up such an attitude seriously. To suppose that it would be possible for a person in receipt of a superannuation allowance, if a member of a board of guardians, to abuse that position by diverting the funds of the board into his own pocket is absurd. Old officers are, on the contrary, likely to make guardians of the best kind. Familiarity with the details of administration gained from long personal experience fits them to come to reasonable conclusions on points about which the average guardian can only talk nonsense and the prospect of their interfering with the grinding of axes by self-seeking members is not one which the community at large need fear.

FATAL ULCERATIVE STOMATITIS AFTER MEASLES.

IN the *British Journal of Children's Diseases* for March Dr. D. McKenzie has reported a case of a very rare complication of measles—ulcerative stomatitis. A well-nourished girl, aged 18 months, was attacked with measles on March 2nd, 1903. The disease ran a moderate course without complications. On March 29th Dr. McKenzie was sent for because the temperature was 104° F. There was a general rash resembling somewhat that of scarlet fever but it was not definitely punctate and the throat was not sore. All the accessible lymphatic glands were enlarged. The pyrexia and rash lasted for three or four days. On April 18th there was fine branny desquamation and the glands had become normal except two left submaxillary glands which were large and hard. On the alveolar margin of the gum above the left upper lateral incisor tooth was an ulcer three millimetres in diameter with a grey rough floor and undermined edges. It was surrounded by red and swollen mucous membrane. During the next few days the temperature was high, the ulcer enlarged, and the submaxillary glands became larger and semi-fluctuating. On April 24th a glandular abscess was opened and scraped under chloroform. The ulcer was scraped, broken-down tissue reaching to the periosteum was removed, and the raw surface was painted with carbolic acid. On the following day the roseolous rash recurred with a temperature of 104° and diarrhœa. The abscess cavity slowly filled up but the ulcer on the gum gradually increased in depth and extent. At the same time the general condition improved. The ulcer was again scraped and painted with carbolic acid. It extended from the alveolar margin of the gum above the incisor and canine teeth to the junction of the mucous membrane of the gum and cheek. Ten days after the appearance of the second rash desquamation was observed. On May 7th the ulcer was scraped for the third time. The left submaxillary region was occupied by a hard brawny mass and the left cheek was red and œdematous. On the 16th the rash appeared for a third time and was duly followed by desquamation. During the next six weeks there was local improvement: the ulcer ceased to spread, the inflammation of the cheek diminished, and the submaxillary induration showed signs of absorption. But the wound enlarged by disintegration of the subcutaneous tissue. On June 17th there was evidence of cerebral complication—vomiting, transient loss of consciousness, photophobia, and retraction of the head. On June 28th the patient died comatose. The necropsy showe alveolar abscess yielded post mortem a culture of the staphylocccus pyogenes aureus. The roseolous rashes were probably due to septic absorption. In the Transactions of the Pathological Society of London for 1887 Mr. Jonathan Hutchinson, jun., reported a somewhat similar case but death seemed to have been due to miliary tuberculosis. The patient was a child, aged 21 months, and the ulcers in the mouth persisted for nine months. Such cases appear to be due to the breaking down of the powers of resistance of the body to the invasion of pathogenic microbes by an attack of measles.

WOMEN INEBRIATES.

THERE is no need to dwell on the misery and degradation which follow when a woman becomes a drunkard. But there is every reason why efforts for her reclamation should excite interest and coöperation. At a retreat for such cases at Fallowfield, Manchester, two classes are received. One consists of persons of education who have fallen into the habit of drinking and they employ themselves "in the lighter domestic duties" and in needlework. A smaller fee is paid by patients of the industrial class and they are occupied in more menial household work. "No patient can be admitted to a retreat except at her own request, signed before a justice." She may sign for one or two years' detention, those signing for two being the minority. The report says that by the end of the first year they have become aware of their weakness and of the strength required before they can face temptation. The treatment is simple, without fads: "rigid abstinence, no drugs, cheerful industry, regular exercise, and a sympathetic atmosphere of religious and moral influence." The home has only accommodation for 25 patients and to show how much it is needed and trusted the applications for admission last year were 125, of which 26 were successful.

ISLINGTON MEDICAL SOCIETY.

A MEETING of this society was held on March 22nd, Dr. B. G. Morison being in the chair. Dr. Morison read a paper on the Comparative Merits and Effects of Prescribing and Dispensing in Medical Practice. He maintained that patients could pay, and were willing to pay, both practitioner and druggist. Even in club practice this arrangement had been found to be possible and druggists were not averse to reducing charges in favour of the poor. The custom of prescribing on the part of druggists was largely the outcome of dispensing by medical men. He questioned whether the profits alleged to accrue from the dispensing system were much, if anything, in excess of the expenses and even losses which it entailed. From a professional point of view the practice of dispensing was indefensible. Dr. G. A. Heron stated that during the period from 1869 to 1871 the general practitioners of Margate, with one exception, at his suggestion ceased to dispense. He found on inquiry that in 1903 there were only three practices in that town in which dispensing was carried on and that the medical practitioners as a body strongly objected to return to the original system. He also mentioned the fact that in Scotland prescribing practice was the rule. Mr. J. Smith Whitaker also spoke in favour of the discontinuance of dispensing which he thought would be feasible if medical men in any district would unite for this purpose. Dr. H. Fraser Stokes, Dr. E. S. Tait, and Dr. A. Reid also preferred prescribing but would like to be convinced as to its practicability. Dr. Alexander Morison spoke in similar terms but held that the vested interests of dispensing practitioners must be taken into account. Mr. T. D. Jago saw no need to change the method now existing and considered prescribing in general practice to be impossible. Dr. J. G. Glover, though accustomed to prescribe and expressing some sympathy with the change proposed, was of opinion that it would bear hardly on the poor, especially in London. Any attempt to press it would be unjust as well as impolitic and would tend to drive patients to the prescribing druggist. The interests of the poor deserved every consideration and though much might be done to promote a better understanding with druggists the liberty of medical men who preferred to dispense must not be interfered with. Dr. B. G. Morison proposed to move at the next meeting of the society that a committee should be appointed to inquire into the questions in dispute. This was agreed to.

LEPROSY IN NEW SOUTH WALES.

FULL clinical histories of the patients admitted during 1901 into the New South Wales leper lazaret are given in an official report by Dr. J. Ashburton Thompson, chief medical officer of the Colonial Government and president of the Board of Health. The lazaret is at Little Bay near Sydney. On Jan. 1st, 1901, there were 11 persons under detention. During the year ten persons were reported to the Board under the Leprosy Act, 1890, as being suspected lepers and nine of them were ultimately admitted to the lazaret under warrants. During the year there were five deaths and on Dec. 31st, 1901, there remained under detention 15 persons, including nine whites, four Chinese, one Javanese, and one South Sea Islander. In his remarks on two of the cases Dr. Thompson refers to instances in which the lesions of leprosy have been erroneously attributed to syphilis.

DEATHS AND QUACK MEDICINES.

AT an inquest held on March 30th Mr. Troutbeck inquired into the death of a child aged seven months. Medical evidence was given to the effect that the child weighed only nine pounds and died from meningitis set up by improper feeding. The mother stated that she had fed the child on tinned milk and a food prepared by a local druggist. One of the jurors raised a question as to the sale of foods and pointed out that they were sold as foods fit for children. The coroner said that in the present state of the law the sale of these foods by means of enticing advertisements was allowed and there was not the slightest doubt that this was the cause of a great deal of disease and death. The same remarks applied to patent medicines but in their case the State made an immoral profit on their sale. We are glad to be able to agree with Mr. Troutbeck. The false statements which are made in advertisements are only too flagrant and whether the Government wishes so or not the revenue stamp on patent medicines is taken as an endorsement of the statements about the medicines which are made by the proprietors. A morning contemporary publishes a series of police regulations which have recently been issued in Lübeck regarding unqualified practitioners and very admirable they are:—

> Persons wishing to practise medicine professionally without being approved by the State must notify their intention to the Medical Bureau. They must immediately report, with the name, age, and residence of the patient, if they advise or treat a person suffering from fevers and diseases of an inflammatory nature. The rules regarding advertisements are very stringent, reading as follows: Public advertisements by non-approved persons are forbidden, in so far as they are calculated to mislead concerning the training, capacity, or success of such persons, or contain boastful promises. Public advertisement of the objects, apparatus, methods, or means which are applied for the prevention, alleviation, or cure of illness is forbidden, when (*a*) superior power over and above their true worth is attributed to such objects, apparatus, methods, or means, or the public is misled by the manner in which they are described; or when (*b*) the objects, apparatus, methods, or means, by the nature of their construction or quality, are calculated to bring about injuries to health. These regulations are to come into force on May 1st and any contravention of the same will be punished by a fine not exceeding 150 marks or by imprisonment.

We commend the rules regarding advertisements to the Commissioner of Police in London and the watch committees in the provinces. If something similar could be carried out here it would bear hardly on those newspaper proprietors who insert lying advertisements of the kind issued by Pointing and "Dr." McLaughlin and upon that disgraceful quack, "Dr." Bell who scatters his dirty pamphlets broadcast through the assistance of His Majesty's Postmaster-General. Any respectable magazine or newspaper should be ashamed to take money for inserting such advertisements as those to which we have alluded. In this connexion we see that Pointing or the Century Thermal Bath Cabinet Company has been summoned at Marlborough-street police-court regarding his *Magic Foot Drafts* and for selling the same without a stamp. A fine was imposed of 10*s.* and costs.

THE SPOROZOA IN RELATION TO DISEASE IN MAN AND ANIMALS.

IN the fifth lecture[1] delivered by Professor E. A. Minchin on March 28th at University College, London, the life-histories of certain sporozoa parasitic on man and birds were dealt with, especial attention being given to halteridium, a form found in birds, and to the trypanosoma, or flagellate phase of the same, found in animals and man. Trypanosomes have been found in certain countries to cause the disease called sleeping sickness. The halteridium is a minute curved parasite which is found within the red corpuscles of birds bent in a semicircular form around the nucleus. Professor MacCallum of Toronto showed from a study of halteridia some years ago that a process of conjugation (sexual union) occurs in the body of birds. Mosquitoes which bite birds—e.g., the owl—infected by the halteridium serve as the intermediate hosts within the gut of which three forms of halteridia are developed—viz., an indifferent or neuter form (ookinete), a female form (trypanosoma), and a male form (trypanosoma). The first of these forms multiplies by fission, the second (female trypanosoma) by a sort of parthenogenetic reproduction, while the third (male trypanosoma) multiplies by repeated division and then dies. No conjugation between the male and female trypanosoma forms occurs in the mosquito's stomach and therefore the male trypanosomes must perish of necessity if forced to remain in the mosquito's body. Only in the blood of birds is conjugation known to occur. The life processes are as follows for each form as observed in the blood of birds. The ookinete first extrudes a droplet of protoplasm from the lower end of its body charged with pigment granules. Its nucleus now divides unequally into two parts by karyokinesis (macro- and micronuclei) and a spindle of fibres develops from the smaller part (micro-nucleus). This spindle structure ultimately gives rise to the flagellum, undulating membrane, and myonemes of the trypanosoma. The female form undergoes a cycle of changes similar to the above ookinete form, except that the micro-nucleus divides to form eight pairs of small nuclei which then undergo degeneration. The large nucleus (macro-nucleus) now divides unequally into macro- and micro nuclei and a process of evolution is now gone through similar to that of the ookinete form, terminating in the production of a flagellate female trypanosoma. The male form undergoes division of the micro-nucleus into eight pairs of granules which arrange themselves radially around the macro-nucleus as a centre. Each pair of granules collects around itself a mass of protoplasm, leaving a central mass of residual protoplasm around the macro-nucleus which now degenerates and dies. The eight peripheral nucleated masses are now separated off and each develops a flagellum with mantle and fibres (male trypanosome form). In the body of the mosquito these three forms multiply so long as there is abundance of blood. In case of "famine," however, when the mosquito has not fed itself for some hours many of the neuter and male forms die. The female forms, however, penetrate into the epithelium and swarm back again when the mosquito has gorged itself with blood. Conjugation of male and female forms never occurs in the mosquito's body; it is only known to take place in the bird or warm-blooded animals (Schaudinn). The neuter forms and the smaller female forms pass into the circulation of the mosquito and thence into the pharyngeal cavity, whence they are ready to infect a bird or other animal which the mosquito bites. Others enter the ovary of the mosquito and infect the ova, penetrating between the yelk granules and growing within the embryo of the next generation of mosquitoes (hereditary infection). Those which have been inoculated into birds by the bite of the mosquito attach themselves to the red corpuscles of the former by the flagellum and then penetrate within the corpuscles, losing the flagellum and assuming the characteristic curved form (halteridium) once more. At night these endoglobular halteridia issue forth into the blood plasma and some of them develop flagella, swim about freely in the blood (motile forms), while the others remain without flagella (non-motile forms). Both these forms multiply by night, the free-swimming forms re-entering the red corpuscles. Schaudinn, from his studies of these trypanosome forms, anticipates that a trypanosome stage of the malarial parasite will be found in the human body.

THE STATE REGISTRATION OF NURSES.

IT was not to be expected that the manifesto issued by those experts who are opposed to the State registration of nurses, upon which we commented in THE LANCET of April 2nd, p. 946, would be allowed to pass without notice by other experts who take the opposite view. We have now received another manifesto from the Society for the State Registration of Trained Nurses signed by Miss Louisa Stevenson, president of the society and member of the board of management of the Royal Infirmary, Edinburgh; Mrs. Bedford Fenwick, honorary secretary of the society, president of the International Council of Nurses, and Member of the Distinguished Order of the Greek Red Cross; and Miss Isla Stewart, senior vice-president of the society, matron of, and superintendent of nursing at, St. Bartholomew's Hospital, president of the Matron's Council of Great Britain and Ireland, and president of the League of St. Bartholomew's Hospital Nurses. Besides these the signatories include a large number of ladies who are representatives of nursing leagues, vice-presidents of the society, or matrons of hospitals, or who are prominent in educational matters or in various spheres of women's work. We do not notice the name of any medical man. From the purely nursing point of view the manifesto in favour of State registration is as convincing as that against it. If, on the one hand, we have against registration the name of Miss Eva Lückes, matron of the London Hospital, we have in favour of registration the name of Miss Isla Stewart, matron of St. Bartholomew's Hospital. The Bill promoted by the Society for State Registration seeks to establish a central and representative nursing council to which all questions of training, discipline, and other professional matters will be referred and by which a register of trained nurses will be kept. Thus, the society wishes to do for nurses what the General Medical Council does, or is supposed to do, for the medical profession; in fact, it will do more, for "the training schools will certainly in every instance be required to testify that candidates possess the necessary personal qualities." We do not envy the training schools their task in the event of the Bill becoming law; however, as there is no doubt that both those who are against registration and those who are in favour of it are agreed upon the desirability of none but capable, trustworthy women being employed as nurses a meeting might be arranged at which representatives from both sides could attend. Then a conjoint course of action might be arrived at.

---

[1] References to the first, second, third, and fourth lectures will be found in THE LANCET of March 12th, p. 736, and 26th, p. 889, and April 2nd, p. 950.

THE DISTRIBUTION OF PLAGUE.

Plague has been present in our South African colonies since February, 1901, when a suspicious case was reported to the medical officer of health of the Cape Colony as occurring at Cape Town. Three days later this was finally diagnosed as plague. On Feb. 14th an advisory board was appointed and a quarantine station was prepared to which "suspects" were removed. Between February, 1901, and August, 1902, 907 cases were officially reported, but from August, 1902, to March, 1904, only occasional cases were notified until for the week ending March 5th, 1904, there were eight cases reported at Port Elizabeth. For the week ending March 12th there were 3 further cases reported at East London and 3 at Uitenhage. Plague-infected rats were found at Port Elizabeth and at East London but in the Cape Town and Harbour Board area of 176 rats examined during the week none was affected with plague. In Natal plague first appeared on Dec. 5th, 1902, between which date and August, 1903, when the disease was practically stamped out, 223 cases had been notified. Durban was the heaviest sufferer, being a seaport, and there 174 cases were notified. In the Transvaal plague appeared early in March, 1904, and a telegram from Lord Milner dated April 2nd states that on that date the position was as follows: Total number of cases 75—in whites 9, in coloured persons 2, in Asiatics 51, and in natives 13. Suspected cases: whites 6, coloured persons 2, Asiatics 6, and natives 36; total 50. Ascertained deaths: whites 7, Asiatics 49, and natives 6; total 62. Suspected deaths: natives 5.

THE CASSEL FUND TRAVELLING OPHTHALMIC HOSPITAL IN EGYPT.

Our readers will recollect that in the beginning of 1903 Sir Ernest Cassel placed at the disposal of the Egyptian Government a sum of £40,000 to be used for the benefit of sufferers from the diseases of the eye which are so prevalent in Egypt. An object to be kept in view was also the training of native medical men in the diagnosis and treatment of such diseases according to modern methods. The Egyptian Sanitary Department, over which Sir Horace Pinching presides, ultimately decided to establish a travelling ophthalmic hospital or dispensary, the system being that a surgeon should proceed leisurely through the provinces with tents so that patients would not have to make long journeys to obtain treatment. Mr. A. F. MacCallan, who had held various offices at the Royal London Ophthalmic Hospital (Moorfields) was accordingly appointed to organise and to direct the enterprise. In an article, recently published in the *Wochenschrift fur Therapie und Hygiene des Auges* Dr. Alfred Osborne states that this system of travelling ophthalmic hospitals, now introduced into Egypt, originated about ten years ago in Russia where it has proved very successful. One of the first advocates of these Russian hospitals was von Bellarminow and their work has been described by Walter of Odessa and Andogsky of St. Petersburg. They are supported by a fund instituted by the Empress Marie Alexandrowna. In the year 1894 there were 21 of them and in 1901 there were 32. Dr. Osborne then goes on to describe what he saw on a visit made to the Egyptian travelling hospital while it was stationed near the town of Menouf in the west of the Nile Delta. It consisted of eight Indian tents and a kitchen of sun-dried bricks. The largest tent was used for operations of which on an average six were performed daily, about five-sixths of the total being operations for entropium (trichiasis). There were two tents for the accommodation of in-patients, only the more severe cases, especially those which required intra-ocular operations, being admitted. In another tent out-patients were treated by Mr. MacCallan's Arab assistant trained in Cairo. Including this assistant the staff of nurses and servants consists of about ten persons for whose accommodation three tents are provided. Great numbers of patients come seeking treatment and the large proportion of females who present themselves shows that the hospital has secured the confidence of the Mahomedan population.

RADIO-ACTIVITY A PROPERTY OF THE DROITWICH BRINE BATHS.

We have received a communication from Dr. P. A. Roden and Dr. John Wilkinson in which it is shown that Droitwich brine yields on boiling a gas which exhibits marked radio-active effects. They submitted to Mr. F. Soddy of University College, London, some of the brine, and although only a small quantity, which, moreover, had been standing for at least 36 hours before the test, was taken for the experiment, yet the gas given off proved to be quite distinctly radio-active. Further investigation is being made into the radio-active value of the brine with the assistance of Dr. Alexander Muirhead. It seems possible that radio-activity is an important factor in balneo-therapeutics. Hitherto much of the benefit gained by a course of waters has been ascribed to mere mechanical or thermic action, coupled with that of the constituents dissolved in the water. In the experience of Dr. Roden and Dr. Wilkinson a further explanation in the case at any rate of Droitwich brine must be sought. Cases are constantly met with, they assert, which when placed in all respects under similar conditions at different spas do certainly obtain benefit from one water and not from another, and this apart from internal treatment. It is highly probable, they add, that different reactions may occur from the use of baths containing different constituents and possibly such reactions may be due not only to those constituents but also to varying radio-activity. It seems to us that a fresh, careful, practical study of the waters employed at all the health resorts in this country in the treatment of disease should be undertaken on the lines indicated. It can hardly be supposed, however, that all waters give relief merely because they are radio-active. Such constituents as sulphuretted hydrogen, sulphides, iodides, barium, and calcium salts when present in waters have not only specific effects when employed internally but also when exhibited in the form of baths.

THROMBOSIS OF THE JUGULAR VEINS IN PULMONARY TUBERCULOSIS.

Thrombosis of the jugular veins is a very rare complication of pulmonary tuberculosis. In the *New York Medical Journal* of March 5th Dr. C. J. Aldrich has published a case and reviewed the literature of the subject. After a diligent search he could find only nine recorded cases. In four the thrombosis was due to causes external to the veins, pressure of tuberculous glands or adhesions. In the remaining cases the thrombosis appeared to be due to phlebitis from internal causes. In the case which is related by Dr. Aldrich a woman suffering from advanced pulmonary tuberculosis was seized with severe pain in the left side of the neck. Examination showed fulness of the supraclavicular fossa and a tender, slightly red tumour at the lower part of the internal jugular vein. The pain extended to the upper part of the left chest and arm. The veins of the left side of the neck became enlarged. Three days later there was peculiar puffy swelling of the hand, which did not pit on pressure and felt like an elastic cushion. The swelling increased and extended up the forearm to the middle of the arm. After a week it reached its height when a thrombus could be felt in the axillary vein. The superficial veins of the upper chest on the left side were enlarged and the lower part of the face was slightly swollen. A thrombus could be traced upwards in both the internal and external jugular veins for a distance of over two inches, while below was a hard tender cord which disappeared behind the clavicle. After about two weeks the swelling of the hand began to diminish. The tenderness and swelling at the root of the neck had almost disappeared when she was seized with pain on the right side of the neck where a red and tender swelling similar to that of the left side developed. The supraclavicular fossa was swollen and the superficial veins of the upper chest were enlarged. Three days later the right hand began to swell and soon it reached the size attained by the left. The forearm became affected and the axillary vein could be felt thrombosed. The thrombosis then extended to the basilic vein. The left hand remained swollen until death which took place four weeks after the onset of the thrombosis. Without warning the patient became unconscious, evidently from thrombosis of the sinuses of the brain. Examination showed extension upwards of the thrombus in the internal jugular vein with considerable œdema of the face and neck on that side. A necropsy was not allowed.

INTERNATIONAL CONGRESS OF SCHOOL HYGIENE.

THE first meeting of the International Congress of School Hygiene took place at Nuremberg on April 5th under the patronage of His Royal Highness Prince Ludwig Ferdinand of Bavaria. The direction of the Congress was in the hands of the chairman of the Allgemeiner Deutscher Verein fur Schulgesundheitspflege, Professor Dr. H. Griesbach, with the support of the following foreign societies: Ligue des Médecins et des Familles pour l'Amélioration de l'Hygiène Physique et Intellectuelle dans les Écoles, the Schweizerische Gesellschaft für Schulgesundheitspflege, the Allgemeen Pædologisch Gezelschap in Antwerpen, the Vereeniging tot Vereenvondiging van Examens en Onderwijs, and an English committee formed by representatives of the Royal College of Physicians of London, the Royal College of Surgeons of England, the Medical Officers of Schools Association, the London School Board, the Sanitary Institute, London, and the Incorporated Society of Medical Officers of Health, with Sir Lauder Brunton as President and Dr. James Kerr, the medical officer to the London School Board, as honorary secretary. The inaugural meeting of the Congress was held in the large hall of the Apollo Theatre on April 5th at 9 o'clock and was opened by His Royal Highness Prince Ludwig Ferdinand of Bavaria in person. The chair was taken by Professor Dr. Griesbach, of Mulhausen, who requested the Prince to open the Congress. The Prince said that it was with the greatest pleasure that he declared the first International Congress of School Hygiene open. He welcomed to Nuremberg the delegates from neighbouring States and distant lands. Professor Dr. Griesbach said that no less than 20 States were represented at the Congress and that Turkey and Italy alone were unrepresented. Delegates from the various countries then thanked the Prince and the committee for their welcome to the Congress. Dr. Eichholz, as representative of the University of Oxford, returned thanks on behalf of Great Britain.

THE London County Council has announced that chicken-pox is to be a notifiable disease for a period of four months from April 8th. Every medical man in the administrative county of London has received a notice informing him that in case he should be in doubt as to whether a case under his care is or is not one of small-pox he can without fee obtain the opinion of either Mr. S. Bingham, *formerly* medical superintendent of one of the Metropolitan Asylums Board small-pox hospitals, or of Mr. W. McC. Wanklyn, late small-pox referee to the Metropolitan Asylums Board. Letters should be addressed: Medical Consultant, Public Health Department, 8, St. Martin's-place, Trafalgar-square, W.C. This arrangement will continue until August 7th.

MR. F. W. Lowndes, the honorary secretary of the United Kingdom Police Surgeons' Association, has requested us to state that he will send a copy of the Statutory Declaration and Orders, 1903, to any member of the association or any medical practitioner on receipt of a letter addressed to him at 40, Knight-street, Liverpool, with two penny stamps inclosed. This important official paper gives full details of the increased fees and allowances sanctioned by the Home Secretary to medical witnesses on the recommendation of the Departmental Committee, 1902.

Professor Seeley of King's College, London, proposes to conduct ten geological excursions which should be of interest to all London sanitarians. The object of the excursions will be to examine the main channel of the Thames and some of its tributaries. A beginning will be made on April 23rd at Purfleet where the Thames flows over the chalk.

THE members of the medical staff of the West London Hospital will hold a conversazione, in connexion with the Post Graduate College, at the hospital on Wednesday, April 20th, at 8.30 P.M.

WHO PERFORMED LITHOTOMY ON MR. SAMUEL PEPYS?[1]

BY D'ARCY POWER, F.S.A., F.R.C.S. ENG.,
TREASURER OF THE SAMUEL PEPYS CLUB.

WE celebrate to-night the two hundred and forty-sixth anniversary of one of the great events in the life of Samuel Pepys—the day when he was successfully cut for stone at the house of Mrs. Turner in Salisbury-court, Fleet-street. The recollection of the day was often in his thoughts and the entry in his Diary on March 26th, 1660, is a faithful reflection of his usual state of mind at each return of spring. It runs: "This day it is two years since it pleased God that I was cut of the stone at Mrs. Turner's in Salisbury Court. And did resolve while I live to keep it a festival, as I did the last year at my house, and for ever to have Mrs. Turner and her company with me." Two years later, on March 26th, 1662, the entry is: "Up early. This being by God's great blessing the fourth solemn day of my cutting for the stone this day four years, and am by God's mercy in very good health. ...... At noon came my good guests, Madame Turner,[2] The.,[3] and Cozen Norton and a gentleman, one Mr. Lewin of the King's Life-Guard. ...... I had a pretty dinner for them—viz., a brace of stewed carps, six roasted chickens and a jowl of salmon hot for the first course: a tanzy and two neats' tongues and cheese the second: and were very merry all the afternoon talking and singing and piping upon the flageolette. ...... We had a man cook to dress the dinner to day and sent for Jane to help us." This is but a single example of many such pleasant dinners and in continuation of them we have met here to-night.

But the club is founded to elucidate as well as to celebrate events in the life of Mr. Pepys and I propose to ask to-night who operated upon Mr. Pepys? I do not think that he anywhere mentions the name of the surgeon, but he was on terms of intimacy with two surgeons, Mr. James Pierce and Mr. Thomas Hollier. James Pierce seems to have been under the protection of Lord Sandwich and it was in this manner no doubt that Pepys became acquainted with him. After the Restoration he was appointed surgeon to the Duke of York, Surgeon-General of the Fleet, and Groom of the Privy Chamber to the Queen. He hoped to be appointed surgeon to St. Thomas's Hospital by the influence of the Duke of York when Tom Woodall was killed in a drunken quarrel in 1666, but I do not find that he was ever elected to the office and he must not be mistaken for Mr. William Pearce who was some time a colleague of Mr. Hollier at St. Thomas's Hospital. James Pierce was master of the Barber-Surgeons' Company in 1675 and was at that time surgeon to the King. Although Pierce was well known to Mr. Pepys he does not seem to have consulted him professionally on any occasion and I think we may say with certainty that Pierce was not his lithotomist.

[1] A paper read at the second meeting of the Samuel Pepys Club on March 26th, 1904

[2] Daughter of John Pepys of South Creake and wife of Serjeant John Turner, Reader in Law.

[3] *Her daughter, afterwards Lady Harris.*

Thomas Hollier was a man of different calibre. He was appointed surgeon "for scald heads" at St. Thomas's Hospital in 1638 and on Jan. 25th, 1643-44 he was chosen surgeon to the hospital in place of Edward Molines, surgeon for the cutting of the stone to the hospital, who had left his place to join the King's army at the beginning of the war. Molines was taken in arms against the Parliament at Arundel Castle and was in consequence deprived of his office as surgeon to St. Thomas's Hospital on the day when Hollier was appointed. After the Restoration King Charles ordered the governors to reinstate Molines, but as the place had already been well filled by Hollier the governors were unwilling to displace him. There was a considerable correspondence and the difficulty was solved at last by the appointment of Molines as a fourth or additional surgeon, the stipend of the surgeons being reduced from £40 to £30 apiece.

Mr. Hollier acted as a second warden of the Barber-Surgeons' Company in 1665, when Mr. Serjeant-Surgeon Wiseman was master, and was himself master of the Company in 1673. In 1669 the College of Physicians bought his house and grounds, extending from Warwick-lane to the City walls, for £1200 to build a new college in place of the college in Amen-corner which had been destroyed by the Great Fire. Hollier's position as lithotomist gave him unusual opportunities to perfect his skill and he is said to have cut no less than 30 persons for stone in one year without a single death, a result of which he might be justly proud were he living amongst us now. Hollier seems to have been the trusted medical adviser of Mr. Pepys, for he bled him, gave him sound advice on many occasions, and when Mrs. Pepys was ill he was summoned to attend her, and though a surgeon he refrained from operating. Sir Frederick Bridge, in his recently published book "Samuel Pepys, Lover of Musique" (p. 63), draws attention to certain entries in a volume of the Sloane MSS. at the British Museum.[4] These entries consist of two prescriptions written by Dr. J. M., the second being countersigned by Dr. G. Jolly. The first prescription is headed "Before he was cut for the stone by Mr. Hollier" and is ordered "for Mr. Peapes." It is a soothing draught, such as might still be given with advantage to a patient whose bladder was inflamed. It contains liquorice, marsh mallow, cinnamon, milk, rose water, and the whites of eggs carefully distilled over a slow fire. The dose ordered was six ounces with an ounce of syrup of althea,[5] to be taken daily in the morning and at bedtime. On the next page of the Sloane MS. is a second prescription for a draught to be in readiness when he was cut. "For Mr. Peapes who was cut for ye stone by Mr. Hollier, March ye 28th (1658) and had a very great stone taken that day from him." This prescription again is for a cooling and demulcent drink such as we still give to a patient whose mouth is parched after an operation. Its chief constituent was lemon juice to which a little syrup of radishes was added. It shows that Mr. Pepys was expected to be feverish after the operation, but the surgeons did not think he would be collapsed or dangerously ill, for the prescription especially mentions that musk was not to be employed and we know that musk in those days was held to be as sovereign a remedy for collapse as is alcohol now. Indeed, few people died in a regular way until they had received a viaticum of musk. It is curious that the prescription should be dated March 28th when Pepys says repeatedly that he was operated upon on March 26th, but we all know that there are other and similar discrepancies of date in the Diary which can in no way be reconciled.

I can find nothing about Dr. Jolly, who signs the prescription, except the reference to him under date, Feb. 27th and 28th, 1662, where Pepys says about a demonstration of anatomy at the Hall of the Barber-Surgeons: "Dr. Scarborough upon my desire and the company's did show very clearly the manner of the disease of the stone and the cutting and all other questions that I could think of ...... how the water comes into the bladder through the three skins or coats just as poor Dr. Jolly has heretofore told me." It appears from this passage that Dr. Jolly had died between the time Pepys was cut and the date of his beginning the Diary in January, 1659-60. There is no mention of Dr. Jolly in the Roll of the College of Physicians, nor was he a graduate of the University of Oxford.

The initials Dr. J. M. at the foot of each prescription stand, I have very little doubt, for Dr. James Moleyns, the leading lithotomist of his time, father of Edward Molines referred to above, and in all probability the master and teacher of Thomas Hollier. I feel a personal interest in James Moleyns because he was a predecessor in the great hospital of St. Bartholomew which I have the honour to serve. He held the office of "surgeon for the stone" both at St. Bartholomew's and at St. Thomas's Hospitals. At a time when medicine and surgery were absolutely divorced and surgery held a very inferior position James Moleyns was one of the very few people licensed by the College of Physicians to administer internal medicines in surgical diseases. His licence is dated Sept. 24th, 1627. He died in 1686 and is buried in St. Bride's, Fleet-street.

We have some interesting information in the books at St. Bartholomew's Hospital about Dr. James Moleyns or Mullins. He succeeded Mr. Robert Murrey, surgeon to the Lock Hospital, in 1622 and after a conference between the governors of St Bartholomew's and those of St. Thomas's Hospitals duties were assigned to him in the following order :—

> Vicesimo die Januarii Anno. Dni. 1622-3.
>
> It is ordered by the Governors of this Hospitall that James Mullins Chirurgion in consideracon of his care and paynes which he is to take in cuttinge and cureinge of poor diseased p'sons of the Stone, and the greifs and Malladies hereunder named, brought to the sev'all hospitalls of St. Barth'ewes and St. Thomas in Sowthwarke, shall have the yearly stipend of xxx*li.* per anm. from XXmas last past soe longe as he shall [illegible] to the good likeinge of the Governors of the [illegible] of his said stipend to be paid him quarterly [illegible] the other xv*l.* from St. Thomas' Hospll. and he [illegible] pounds of towe for every patient for theire more easie and warmer dressinge.
>
> For the annuall stipend of thirty pounds I under take (wth. God his helpe) my best skill and experience the manuall operacon and chirurgicall cuer of these issuinge Maladies viz.
>
> The Cureinge by insition the stone in the yard or Bladder.
>
> The cureinge of the rupture or falling downe of the Intestines or gutts into the Codds by Cuttinge.
>
> The Cureinge by Insition the Carnosity or fleshie substance in the Codds.
>
> Also the Curinge of Wenns by Insition.
>
> Desiringe that for every patient I may have the allowaunce of 2 pounds of towe for theire easier and warmer dressinge.

It will appear from these statements that the governors of the two hospitals appointed a special surgeon for the treatment of those conditions which had so far fallen into the hands of quacks (lithotomists, hernia specialists, and fistula curers) that the ordinary surgeons left them untended. It was no doubt due to these wise orders and to the appointment of suitable persons at the hospitals that lithotomy and hernia once more came to be considered a part of legitimate surgery. Now I think it is clear from the facts I have brought together that Mr. Pepys was operated upon by Mr. Hollier who had called into consultation his old master, Dr. James Mullins. He thus came under the care of the two best lithotomists of the time and I suspect that they used more than two pounds of tow for his dressings. If Mr. Hollier was his lithotomist there is a good reason why he should have taken rooms at Mrs. Turner's in Salisbury-court, for he would wish to be as near as possible to his surgeon who was living in Warwick-lane.

[4] Sloane MSS., No. 1536, f. 63, margin.

[5] The syrup of althea itself was: ℞ Roots of Althea two ounces: roots of grass, asparagus, Liquorice cleansed: Raisons stoned: ana half an ounce. Taps of marsh mallow: leaves of mallow, Pellitory: Burnet: Saxifrage: Plaintain: White and Black Maidenhair: ana M. (a handful) i: Red Cicers an ounce: of the four greater and lesser cold seeds ana three ounces. Infuse them a whole day in clear water, lb. vi. Boil to the consumption of two pounds: then strain and press and with sugar, lbs. iiss. make a syrup in Balneo Mariae according to Art.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 8, 1826.

Case of apparent Superfœtation. By JOSEPH FITHIAN, M.D., of Woodbury, N.J.

IT has been a disputed point in physiology, and is to this day, whether superfœtation does ever take place in the animal economy.

We know, that nature, in the production of our race, generally pursues an undeviating and uniform course, which would lead us to believe, that whether two or more children are born at one birth, they are begotten nearly together, if not at the same time.

Many facts, however, of a curious and interesting nature are from time to time communicated, which appear to be exceptions to this general rule; and, among others, the following favours the hypothesis that superfœtation does occasionally occur.

Mrs. W. was delivered of a fine healthy child at the full time without any difficulty attending the birth.

After the labour was over, and the assistants were preparing to get her to bed, they discovered something which, from its uncommon appearance, induced them to call my attention to it.

Upon examining this substance, it proved to be a fœtus three or four inches long, with its membranes and placenta complete; all of a fresh, healthy appearance, and had undoubtedly been alive and healthy up to the time of the labour.

I have frequently seen abortions at every period of gestation, and from the appearance of this fœtus, had I been called to see it without any knowledge of the circumstances, I should without hesitation have pronounced it an abortion at the third or fourth month. It had the large head, small extremities, and general appearance which characterize a fœtus at that age.

I have communicated the above fact, as it occurred to me in my practice. I will leave it for others to draw their inferences.—*Ibid.*[1]

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at the *Board Room, Suffolk-street, S.W.*, on *March 24th*, Dr. F. H. CHAMPNEYS being in the chair, when the following business was transacted.

1. On consideration of applications for approval of certificate as a qualification *under Section 2 of the Act* the certificate of the following institution was approved: National Maternity Hospital, Dublin.

2. The following institutions were approved for the training of midwives under Section C of the rules, subject to an undertaking to comply with the requirements of Section E of the rules: Birmingham Workhouse Infirmary, Bristol Royal Infirmary, Brownlow Hill Workhouse Hospital, Liverpool, *Essex County Cottage Nursing Society*, Gloucester District Nursing Society, Hull Lying-in Charity, and Ipswich Nurses' Home.

3. The following registered medical practitioners were approved as teachers under Section C 1 (3) of the rules: Mr. A. B. Batley, Mr. A. B. Calder, Dr. John Gutch, Mr. E. S. Hoare, Dr. Wilfred R. Kingdon, Dr. E. J. Maclean, Dr. Thomas Pimley, and Mr. Penrose L. W. Williams.

4. The following certified midwives were approved under Section C 1 (2) for the purpose of signing certificates of attendance (Forms III. and IV.): Eleanor Heatley, E. S. Sibery, E. S. Tate, and Bessie M. Worrall.

5. After consideration of applications for certificates the
names of 849 women [illegible] the Act
and ordered for entry bows the
separate numbers of present
entered on the roll: F Ireland,
1; Obstetrical Society [illegible], Rotunda Hospital, 43;
Coombe Hospital, 12; Queen Charlotte's Hospital, 52; Liverpool Lying-in Hospital, 15; British Lying-in Hospital, 2; Glasgow Maternity Hospital, 32; St. Mary's Hospital, Manchester, 53; City of London Lying-in Hospital, 6; Royal Maternity Hospital, Edinburgh, 5; Salvation Army Maternity Hospital, 3; and women in *bonâ-fide* practice, *July, 1901, 2238; the total enrolled being 3415.*

MEDICINE AND THE LAW.

The Conviction of an Abortionist.

AT the Old Bailey on March 25th Mr. Justice Grantham passed a sentence of seven years' penal servitude upon Bertha Bandach, an elderly German woman, who cannot be regarded as having been treated with undue severity. She was convicted of manslaughter upon facts which, strictly speaking, laid her open to indictment for murder, for she had brought about the death of a woman by procuring abortion
upon her,
Moreover, i
thus for the
regard her
[illegible]

five years' penal servitude. An interesting question of evidence was raised during her trial owing to an attempt made to suggest that traces of injury inside the uterus of the deceased discovered by post-mortem examination might have been accidentally inflicted by the victim herself in using a vaginal syringe. In addition to medical testimony as to the difficulty which she would have found in reaching the spot indicated, the Treasury claimed the right to give evidence of similar "accidents" having happened in other cases with which the prisoner had been associated. This evidence was admitted by the judge and it is clearly of great importance that it should be so as the suggestion of an innocent accident, however unconvincing it might seem to medical men, is a natural defence to be raised at the trial of an abortionist. *It is to be hoped that the operation of the* Midwives Act when it comes more fully into force will prevent *such women* as Bandach *from carrying on their* trade, as she did, behind brass plates bearing the inscription of "midwife." The case also points to the defects of the existing system of death certification. The deceased woman would apparently have been buried without further inquiry, owing to the medical man who attended her when dying having been misled by statements as to her habits of life and previous condition of health, had not another practitioner who had treated her after the former miscarriage, which has been mentioned, communicated with the coroner. Bandach will be under restraint for some years to come but a woman who has found that the criminal *exercise of such skill as she may possess* can be made profitable is not likely to be reformed and it is for the safety of the public as well for the punishment of her offence that she is imprisoned.

Messrs. Burroughs, Wellcome, and Co. and the "Tabloid" Trade Mark.

The Court of Appeal has upheld the judgment of the late Mr. Justice Byrne refusing to remove from the register of trade marks the word "tabloid," placed there under the Patents, Designs, and Trade Marks Act of 1883. The appeal was made solely upon this issue, the question of the substitution of other wares for "tabloids," when "tabloids" were ordered, not being again raised. The question for the decision of the court, although strictly speaking one of law, involved really, as Lord Justice Vaughan Williams pointed out, a matter of fact as to what the word "tabloid" actually conveyed to those who heard it at the date of registration in 1884. The substance of the judgments *delivered* was that according to recent decisions a word registered as a "distinctive fancy word not in common use" must not be descriptive but need not be absolutely unsuggestive of the goods to which it is applied. Upon reviewing the cases dealing with the matter the court was of opinion that tabloid although "*suggestive*" was not at the time of registration "descriptive." Both Lord Justice Stirling and Lord Justice Cozens Hardy expressed themselves as not entirely free from doubt, the latter questioning whether ten years ago the word "tabloid" would have been left upon the register and adding "*the swing of the judicial* pendulum has been very great and the extreme point of the swing is to be found, I think, in the present case." No doubt Messrs. Burroughs, Wellcome, and Co., who are to be congratulated upon having maintained the judgment given in their favour on Dec 14th, 1903, are to some extent at a disadvantage owing to the public adoption of the word which they invented for their own benefit. "Tabloid" is now a convenient word for the expression of "much in a small compass," a sort of colloquial synonym of *multum in parvo*, and no doubt many people would be surprised to learn that 20 years ago the term was unknown to them.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8076 births and 5464 deaths were registered during the week ending April 2nd The annual rate of mortality in these towns, which had been 19·0, 19·7, and 18·7 per 1000 in the three preceding weeks, was again 18·7 last week. In London the death-rate was 18·8 per 1000, while it averaged 18·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 8·4 in Walthamstow, 9·0 in Hornsey, 9·4 in Leyton, 11·0 in Willesden, 11·2 in Ipswich, 11·8 in Devonport, 12·3 in Reading, and 12·5 in East Ham and in Hastings; while the highest rates were 23·6 in Birkenhead, 23·9 in Swansea, 24·5 in Birmingham and in Manchester, 24·6 in Tynemouth, 24·8 in Warrington, 25·0 in Bury, 25·3 in St. Helens, and 28·6 in Rochdale. The 5464 deaths in these towns last week included 640 which were referred to the principal infectious diseases, against 500, 540, and 532 in the three preceding weeks; of these 640 deaths 234 resulted from whooping-cough, 211 from measles, 71 from diphtheria, 58 from diarrhœa, 32 from scarlet fever, 26 from "fever" (principally enteric), and eight from small-pox. No death from any of these diseases was registered last week in Hastings, Bournemouth, Southampton, Northampton, Ipswich, Burton-on-Trent, Handsworth (Staffs.), Kings Norton, Wigan, Barrow-in-Furness, Halifax, Rotherham, or Stockton-on-Tees; among the other towns the highest death-rates from these diseases were recorded in Hanley, Birmingham, Coventry, St. Helens, Warrington, Bolton, Bury, Manchester, West Hartlepool, and Swansea. The greatest proportional mortality from measles occurred in Norwich, Hanley, Wallasey, St. Helens, Bury, Manchester, Salford, Burnley, and Leeds; from diphtheria in East Ham, and Hanley; and from whooping-cough in Wolverhampton, Birmingham, Coventry, St. Helens, Warrington, Bolton, West Hartlepool, Gateshead, and Swansea. The mortality from scarlet fever, from "fever," and from diarrhœa showed no marked excess in any of the large towns. Of the eight fatal cases of small-pox registered in these towns last week, three belonged to London, two to Tynemouth, one to Nottingham, one to Oldham, and one to Gateshead. The number of small-pox patients remaining under treatment in the Metropolitan Asylums hospitals, which had been 54, 74, and 110 on the three preceding Saturdays, had further risen to 126 on Saturday, April 2nd; 42 new cases were admitted during the week, against 21, 26, and 54 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 1570, against 1601, 1624, and 1585 at the end of the three preceding weeks; 153 new cases were admitted during the week, against 192, 176, and 145 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 414, 375, and 383 in the three preceding weeks, declined again to 370 last week, but were 132 above the number in the corresponding period of last year. The causes of 57, or 1·0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Bradford, Newcastle-on-Tyne, and in 43 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, St. Helens, Warrington, Manchester, Burnley, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21·5, 23·0, and 22·3 per 1000 in the three preceding weeks, further declined to 20·6 per 1000 during the week ending April 2nd, but was 1·9 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·6 in Leith and 17·5 in Aberdeen to 22·4 in Greenock and 26·2 in Perth. The 681 deaths in these towns included 23 which were referred to measles, 23 to whooping-cough, nine to diarrhœa, five to small-pox, five to scarlet fever, four to "fever," and three to diphtheria. In all, 72 deaths resulted from these principal infectious diseases last week, against 68, 85, and 86 in the three preceding weeks. These 72 deaths were equal to an annual rate of 2·2 per 1000, which was also the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 20, 23, and 22 in the three preceding weeks, rose again last week to 23, of which 12 occurred in Glasgow, four in Dundee, and four in Paisley. The deaths from whooping-cough, which had been 21, 24, and 29 in the three preceding weeks, declined again to 23 last week and included eight in Glasgow, five in Dundee, three in Edinburgh, two in Aberdeen, two in Paisley, and two in Leith. The fatal cases of diarrhœa, which had been 13, 18, and 15 in the three preceding weeks, further declined last week to nine, of which seven were registered in Glasgow and two in Dundee. The deaths from small-pox, which had been five, two, and seven in the three preceding weeks, declined again to five last week, and all occurred in Glasgow. The fatal cases of scarlet fever, which had been two in each of the two preceding weeks, increased last week to five, of which three were recorded in Glasgow, where three of the four deaths from "fever" were registered also. The deaths referred to diseases of the respiratory organs in these towns, which had been 156, 185, and 165 in the three preceding weeks, further declined last week to 157, but were 36 in excess of the number in the corresponding period of last year. The causes of 31, or nearly 5 per cent., of the deaths in these towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·3, 27·7, and 30·4 per 1000 in the three preceding weeks, declined again to 28·5 per 1000 during the week ending April 2nd. During the 13 weeks ending on that date the death-rate has averaged 28·0 per 1000, the rate during the same period being 18·3 per 1000 both in London and in Edinburgh. The 207 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 14 from the number in the preceding week and included 20 which were referred to the principal infectious diseases, against 11, 20, and 14 in the three preceding weeks; of these, 11 resulted from whooping-cough, four from measles, two from "fever," two from diarrhœa, and one from scarlet fever, but not any from small-pox or diphtheria. These 20 deaths were equal to an annual rate of 2·8 per 1000, the death-rates during the same period from the principal infectious diseases being 2·3 in London and 0·6 in Edinburgh. The fatal cases of whooping-cough, which had been six, 13, and five in the three preceding weeks, rose again last week to 11. The deaths from measles, which had been four and five in the two preceding weeks, declined again to four last week. The 207 deaths in Dublin last week included 36 of children under one year of age and 59 of persons aged 60 years and upwards; the deaths of infants showed a considerable decline, while those of elderly persons were slightly in excess of the number in the preceding week. Seven inquest cases and five deaths from violence were registered, and 84, or more than two-fifths, of the deaths occurred in public institutions. The causes of nine, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: — Fleet Surgeon W. G. Stott to the *Lancaster*. Staff Surgeon H. B. Hall to the *Endymion*. Surgeons: G. Taylor to the *Endymion;* H. G. T. Major to the *Bulwark;* E. H. Ross to the *Lancaster;* A. D. C. Cummins, C. W. Woods, and B. R. Bickford to the *Vivid*, additional, N. S. Meiklejohn, H.

Woods, C. J. Boucher, F. M. V. Smith, D. H. Vickery, and W. G. M. Anderson to the *Fire Queen*, additional, J. C. Bringham, W. P. Yetts, G. H. S. Mills, R. H. St. B. E. Hughes, G. D. Walsh, A. R. Davidson, E. Kenny, and E. P. G. Causton to the *Pembroke*, additional, L. C. E. Murphy, E. R. Townsend, and A. R. Schofield to the *Wildfire*, additional, all for disposal; and P. D. Ramsay and F. J. Gowans to the *Vivid*, additional, for Plymouth Hospital.

Fleet Surgeon Charles James has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets (dated Jan 4th, 1904).

The notice which appeared in the *London Gazette* of March 22nd, relative to the withdrawal from His Majesty's Naval Service of Staff Surgeon Henry Baker Hall is cancelled.

ROYAL NAVAL VOLUNTEER RESERVE.

Fielding Charles Whitmore has been appointed Surgeon (dated March 31st, 1904).

ROYAL ARMY MEDICAL CORPS.

Major H. Carr is transferred from the Poona to the Mhow District. Lieutenant-Colonel J. L. Hall is appointed to the command of the Station Hospital, Quetta. Lieutenant H. H. Kiddle is transferred from the Bombay to the Poona District.

VOLUNTEER CORPS.

Rifle: 4th Volunteer Battalion the Cameronians (Scottish Rifles): Brigade-Surgeon-Lieutenant-Colonel J. Macfie, Senior Medical Officer, Scottish Rifle Volunteer Infantry Brigade, resigns his commission and is granted the honorary rank of Surgeon Colonel, with permission to wear the prescribed uniform (dated March 26th, 1904). 1st Volunteer Battalion, the Duke of Wellington's (West Riding Regiment): Alfred Thomas Griffiths to be Surgeon-Lieutenant (dated March 26th, 1904) 2nd Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant-Colonel R. T. Cæsar resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform (dated March 26th, 1904). 3rd London: Surgeon-Lieutenant T. W. Parry to be Surgeon-Captain (dated March 26th, 1904). 2nd (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon Captain H. O. Donald to be Surgeon-Major (dated March 26th, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Aberdeen Company: The undermentioned Lieutenants to be Captains:—W. A. I. Fortescue (dated March 26th, 1904); F. Kelly (dated March 26th, 1904); A. Ogston (dated March 26th, 1904); and T. Fraser (dated March 26th, 1904). The Glasgow Companies: Robert Yuill Anderson to be Lieutenant (dated March 26th, 1904).

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

West Yorkshire: S[illegible] Captain G. G. Oakley (Honorary Cap[illegible] Battalion the Duke of [illegible] to be Captain and to c[illegible]).

THE SIR WILLIAM TAYLOR PRIZE.

The Sir William Taylor Prize of 25 guineas has been awarded to Major M. P. C. Holt, D.S.O., R.A.M.C., in recognition of distinguished professional attainments in surgery as evidenced by the returns of operations performed in Ireland. This prize is awarded annually by Sir William Taylor to the executive officer of the Royal Army Medical Corps on the active list, or on full pay employment below the substantive rank of Colonel, who shall, in the opinion of the committee, be most deserving on account of professional or scientific work.

THE WAR IN THE FAR EAST.

At a special sitting of the Medical Subcommittee held in Moscow on the organisation of the two flying hospitals being furnished at the expense of the local merchants' club it was decided, says the *Novosti*, to exclude entirely the female element from the staff to be attached to them. The horses required (45 in number) for their transport about the fighting zone will be procured in Manchuria.

Dental Surgeon H. O. Toone has been posted to Plymouth and Dental Surgeon A. F. A. Howe to Portsmouth.

Correspondence.

"Audi alteram partem."

THE HOLMAN TESTIMONIAL.

To the Editors of THE LANCET.

SIRS,—As treasurer and secretary of the Holman Testimonial Fund we ask your insertion of this letter and first list of subscribers. It is very rare in our own profession or any other that so consistent a course of public work and effort in the cause of charity can be found. In disregard of personal interest Dr. Holman has for the last 50 years taken more than his share, as a worthy successor to the Martins of Reigate, of the labour of love which builds up our medical charities. As founder and secretary of the South-Eastern branch and as treasurer of the British Medical Association he has advanced the progress of the Association and improved its finances, while as treasurer for 20 years of Epsom College he has fathered it and tided it over many difficulties until it is now recognised as a great public school with a greater future before it. It seems a worthy object to do something to mark time in such a career. In the church of St. Maria Antiqua in the Roman Forum are pictures of popes with square and round nimbi. The square nimbus is the mark of a living pope and such a one would we place on the head of our friend whom we desire to honour while living and we would do so in the manner most congenial to himself in some help to Epsom College associated with his name. We are sure that those most intimate with his work will be our helpers in this aim which we trust will lose no supporters from any inadequacy on the part of its promoters.

We are, Sirs, yours faithfully,
JOHN H. GALTON, M.D. Lond., Treasurer.
W. A. BERRIDGE, Secretary.

Subscriptions of any amount will be received by Dr. John H. Galton, Chunam, Sylvan-road, Norwood, London, S.E.

THE PAINFUL PRONATION OF CHILDHOOD.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 19th, p. 820, a very useful summary is given of a paper by Professor A. Broca on the "painful elbow" or "elbow-sprain" of childhood. He has evidently overlooked an experimental research into this condition published by Mr. J. Hutchinson, jun., in the *Annals of Surgery* for August, 1885, otherwise your transcriber would scarcely have said that "there has been much uncertainty as to the exact lesion present." "The essential feature," writes Mr. Hutchinson, "of these far more common sprains in early life is the upward displacement of the orbicular ligament, to which I have hitherto found no allusion." There is a preparation in the museum of this college, placed there by Mr. Hutchinson in 1885, showing this condition. The fibres which bind the orbicular ligament to the neck of the radius are torn across and part of the orbicular ligament is wedged in between the head of the radius and the capitellum of the humerus. In considering the production of this condition most writers neglect the part played by the supinator brevis in retaining the head of the radius applied to the capitellum.

In young children, when caught suddenly by the hand and lifted, the supinator brevis is caught unawares and the strain, instead of being caught by this and other muscles, is thrown entirely on the ligaments, especially on the orbicular. There is a danger with the great modern rush of medical literature that valuable papers may be buried and forgotten and for that reason I draw attention to Mr. Hutchinson's paper.

I am, Sirs, yours faithfully,
A. KEITH, M.D. Aberd.
London Hospital Medical College, E., March 25th, 1904.

ON THE OPERATIVE TREATMENT OF RENAL HEADACHE.

To the Editors of THE LANCET.

SIRS,—A letter just received prompts me briefly to record its writer's case, which affords a striking instance of how headache of long standing and apparently due to deficient renal excretion may be permanently relieved by operative procedure. The patient is a married woman, aged 37 years. A year ago she had been subject to intense paroxysmal headaches for a number of years. Remedies proved of little or no use and the patient had been in the habit of shutting herself up and seeing no one during the attacks. She had recently had an attack of acute nephritis of the left kidney, with the result that the headaches had become even more frequent and severe. The patient was sent to Montreux to try the effect of change of climate and called on me first on Jan. 6th, 1903, to ask if I thought some other place would suit her better. She was in a condition of evident suffering, her face was drawn and her aspect was despondent. Her pulse was of somewhat high tension and the urine contained a little albumin. The abdomen was distended, the right kidney was in the neighbourhood of the caput coli and was freely moveable, and the left kidney was slightly moveable. After trying a variety of drugs, galvanism, faradism, compresses, and abdominal exercises with little result beyond rendering the abdomen less tense, I persuaded the patient to go into Professor Roux's clinique at Lausanne with a view to having a thorough examination made of the renal excretion.

On Feb. 25th an examination was made with Luys's bi-ureteral collector, a pill of methylene blue having been administered shortly beforehand. The two collecting tubes showed a nearly equal secretion of urine from either kidney, but the fluid from the left kidney was of a somewhat lighter colour than that from the right. A radiogram gave a negative result as regards stone. Thus, the condition of the kidneys was as follows: a highly moveable right kidney and a slightly moveable left kidney; the right kidney was small though healthy as far as could be ascertained by palpation, the left kidney having recently undergone an acute inflammatory process; no calculus was palpable in the right kidney; there was no indication of calculus in the radiogram of the left kidney; the right kidney functionally was more active than the left kidney, as was shown by the differential collector. With these facts before us the question was whether the headaches depended on the condition of the kidneys, if on one kidney more than the other, and on which, and whether operative interference would be likely to afford relief. Professor Roux decided on operating and selected the left kidney on the following grounds: that as a general rule a moveable left kidney produces more definitely marked symptoms than a moveable right kidney; that a kidney which is freely moveable produces less disturbance than a kidney which merely oscillates on its hilus; and that in the present case the left kidney had been recently inflamed and was probably surrounded by adhesions and that possibly it might contain a calculus.

On March 6th Professor Roux cut down on the left kidney, freed it from adhesions, and stitched it in position. From the date of the operation the headache decreased in intensity. On April 6th the patient came to Glion and on May 18th I saw her for the last time and I find the following entry in my notes as to her condition: "Patient looking remarkably well and bright" On March 7th, just one year after the operation, I received a letter from her, from which I give the following extract: "I have not had one bad headache since I came home and everyone here is simply amazed at the change in me."

If I may venture to trace the sequence of events in this case I should suggest that the slightly moveable left kidney gave rise to an irritative perirenal fibrosis resulting in the formation of a fibrous capsule which prevented the distension of the kidney under the influence of functional congestion. Hence defective excretion on the part of the left kidney, while the right kidney being moveable was not in a favourable condition for undergoing vicarious hypertrophy and doing double duty.

Note.—After perusal of this letter Professor Roux writes me that the headaches are perhaps rather to be regarded as part of a generalised nervous disturbance frequently associated with moveable kidney and to which it has hitherto been the custom to attribute certain forms of neurasthenia. Be the mechanism what it may, the fact remains that the treatment was in this case followed by most satisfactory results. I am, Sirs, yours faithfully,

Montreux, March 10th, 1904. STUART TIDEY.

SULPHONAL POISONING.

To the Editors of THE LANCET.

SIRS,—The following case may interest some of your readers and perhaps they would be able to confirm the diagnosis of sulphonal poisoning from similar cases they may have had. The patient, a colonel in the Royal Army Medical Corps, aged 50 years, while homeward bound from India was suffering from a "cold in the head" and took 20 grains of sulphonal; six or seven hours afterwards he experienced irritation and pain over the ankle joint. This caused him so much discomfort that four hours later he got up and examined his ankle, also noticing irritation at the knee and elbow. He discovered circular patches of erythema, varying in diameter from a quarter of an inch to one inch, over each of the joints above mentioned and also over two metatarsal and two metacarpal joints and one patch on the wrist of the same side. There was some œdema over the ankle, elbow, and metacarpal joints which was confined to the skin only. The redness disappeared on pressure. 30 hours after the irritation was first noticed the patient experienced the sensation of a blister forming, to use his own words, and noticed the exudation of a small quantity of clear serum. He was seen by three or four medical men on board who agreed that it was urticaria and treated him accordingly. I saw him on the third day and noticed two small patches on the abdomen. On the fourth day the patches were less distinct and the irritation was subsiding. I did not see the patient again but he has written saying that it has all disappeared. The patient said that 12 months ago he took 20 grains of sulphonal with a similar but less marked result; it was then put down to the malarial fever from an attack of which he was recovering. He enjoys excellent health, his only trouble being writer's cramp. The peculiarities of the above case are (1) the small amount of sulphonal taken—only one dose; (2) all the patches appeared simultaneously; (3) the position of the patches being, with the exception of two, confined to the neighbourhood of the joints; and (4) the length of time the rash remained, seven or eight days.

I am, Sirs, yours faithfully,
J. L. WHATLEY, M.R.C.S. Eng., L.R.C.P. Lond.
Aston Ingham, Ross-on-Wye, March 29th, 1904.

PNEUMONIA IN EARLY LIFE.

To the Editors of THE LANCET.

SIRS,—The following cases scarcely come under the heading of treatment by opium though minute doses were given in combination with iron. They occurred some years ago and nearly all in the month of March. With one exception they were patients of a Brighton medical charity and were treated at their own homes. All were, except Case 8, treated in the same manner with tincture of iron and tinctura camphoræ composita. In some poultices were applied for a time, followed by the application of camphorated oil, the thorax being then wrapped in wadding. The pallor and depression which pneumonia at times causes in young children have doubtless been often noticed by other observers. The notes are, I regret to say, exceedingly meagre.

CASE 1.—The patient was a boy, aged six years, with pneumonic consolidation of the right lung; the child was very ill. He was treated with tinctura ferri and tinctura camphoræ composita. Recovery ensued.

CASE 2.—The patient was a delicate infant, aged 15 months, with pneumonia of the left lung. There was tenderness on pressure. The child was treated with one minim of tinctura ferri and less than one-minim doses of tinctura camphoræ composita every four hours. Recovery ensued.

CASE 3.—The patient was an infant, aged 11 months, with pneumonia at the base of the right lung. The treatment was: 12 minims of tinctura ferri, ten minims of tinctura camphoræ composita, syrup, and water to one and a half ounces; one-twelfth part to be taken every four hours. Recovery ensued.

[illegible] years, after scarlet [illegible] doors. There was [illegible] ie right lung. The child was treated with tinctura ferri and tinctura camphoræ composita and recovery followed.

CASE 5.—The patient, a man, aged about 25 years, was found to be suffering from consolidation of the right lung. He had not remained in bed, though feeling ill. He was ordered to bed, treated with friction and with liniment and wadding, which latter he soon discarded on account of its heat. He was given tinctura ferri and tinctura camphoræ composita and some strychnia and made a good recovery.

CASE 6.—The patient was a child, aged two years. This little patient was seriously ill with a temperature of 103° F. There were broncho-pneumonia with diarrhœa, brain symptoms, and a brain cry. The diarrhœa—a sequel to castor oil—was troublesome, requiring bismuth and the discontinuance of the tinctura ferri which had been given with the tinctura camphoræ composita. The case was quite despaired of after a few days by me and also by the district nurse The diarrhœa, however, ceased, the brain symptoms passed away, and a complete recovery followed. This was the worst case of illness in the series.

CASE 7.—The patient was an infant, aged six or eight weeks. At the second visit I found pneumonia at the base of, I think, the left lung. Treated with tinctura ferri in one-minim doses a good recovery followed within a fortnight.

CASE 8—The patient, a baby, with pneumonia of the right lung, was treated with salines and small doses of aconite. Recovery ensued.

I am, Sirs, yours faithfully,
EDGAR DUKE, M.D. Durh.
Hove, March 28th, 1904.

TRANSPOSITION OF THE VISCERA.

To the Editors of THE LANCET.

SIRS,—A very [illegible] which I consider wort[illegible] ny experience. On M[illegible] sailor who had fallen into the hold of a ship called the *Kate Thomas*, lying in dock in this port. I found the man suffering from a severe sprain of the left hip-joint. In a *general examination for other possible injuries I* was astonished to find his heart, liver, and spleen situated abnormally as regards the mesial line. His heart was on the right of the mesial line and its apex beat could be seen one and a half inches below and a half-inch to the left of the right nipple. The second sound could be best heard in the first right intercostal space half an inch from the sternum. The liver was transposed to the left and the hepatic dulness, though embracing a field of normal extent, was wholly transposed. The spleen could be felt on the right side The man, whose name is Johan Heidenreich, is a Hollander, aged 41 years. He informed me that in 1880 he went to Amsterdam with the intention of entering the navy. The medical examiners, Dr. Zegars and Dr. Bienendyk, were surprised to find the viscera transposed and though the would-be recruit was quite healthy and sound they could not, in view of his abnormality, allow him to pass. When Heidenreich's physical peculiarity became known in Amsterdam it attracted much attention, an examination being made by Professor Stockfish and nearly a hundred other medical men. A petition was sent to the King praying that Heidenreich might be permitted to join the navy, but apparently the King could not see his way to over-rule the objection of the naval medical examiners, although Heidenreich's visceral abnormalities were not looked upon as in any way detrimental to his *health. The late Dr. Delanus, in* a *clinic relative* to Heidenreich's case, said that he had never seen, nor had he ever met anyone who had seen, such a case, but he believed that in the year he was born—1800—one was recorded in Vienna. Having been rejected by the navy Heidenreich tried for the army but was again rejected on the same grounds. Since 1882 he has been at sea, has sailed to all parts of the world, and was once shipwrecked in the Mediterranean. He has never been ill. He informs me that the Dutch and German journals devoted a good deal of space to his case.

I am, Sirs, yours faithfully,
WILLIAM HARTLAND.
Port Talbot, South Wales, March 29th, 1904.

ECLAMPSIA AND CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—The case mentioned by Dr. J. F. Jennings in THE LANCET of March 19th, p. 793, brings to my mind a similar case to which I was called by a neighbouring practitioner about 22 years ago. The patient was a primipara, about 25 years of age. She had severe fits every few minutes. Labour had commenced, the os being dilated to the size of a five-shilling piece. I suggested the immediate administration of chloroform and the patient was kept under its influence until delivery was effected which was assisted by digital dilatation of the os and then the use of the forceps, and in about an hour the case was terminated, the fits ceasing in the course of another hour. The urine was highly *albuminous. The effect of the chloroform was so gratifying* that I should always do the same again in a similar case and not waste any time in trying other remedies. I have no notes of the case.—I am, Sirs yours faithfully,
Bristol, March 30th, 1904. A. H. HAINES, M.R.C.S. Eng.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Another Indian Municipality warned by Government for Neglect in Sanitary Matters.—Disposal of Contents of Septic Tanks—Increase in the Plague Mortality.—Quarantine for Indian Pilgrims to Mecca.—A Nursing Institute for Madras City.

I HAVE had from time to time to point to the serious shortcomings of Indian municipalities, more especially with regard to sanitary matters, and in some instances the neglect has been so flagrant that the Government has been compelled to deprive the defaulting bodies of their powers. An order has recently been passed by the Government of Madras against the Kumbakonam municipality. In financial matters great defects have been reported but in the sanitary department it appears that the chairman of this muni*cipality "has given no* attention to the supervision of the work of the chief sanitary inspector and his department, and that sanitary duties are neglected, filth is allowed to be deposited all over the town, persons committing nuisances are seldom prosecuted, the markets are in a disgraceful state, the private scavenging service is not progressing, there is no separate night-soil depôt, and the number of latrines and night-soil carts is insufficient for the needs of the population." In ten years the sanitation of this important town has been practically stationary, notwithstanding repeated recommendations by the sanitary officers, and no provision appears to have been made for carrying out any of the recommendations by the council in its annual budgets. The vital statistics of the town are reported as untrustworthy and there is no supervision over the work of the vaccinators. Notwithstanding neglect in every branch of the administration the Government is merely giving the council a warning and will allow the same body to continue in office for the present year. At this rate little progress will be made and I have no hesitation in saying that the council should be at once dissolved and the necessary powers for administration placed in other hands.

I regret to hear that the Lieutenant-Governor of Bengal has listened to the prayer of the Hindu community and has directed the discontinuance of the practice of discharging the contents of the septic tanks installed at a sparsely inhabited part of the river Hooghly several miles up from *Calcutta. Considering that the river is extensively used as* a latrine all along its banks and that drainings into it of all sorts of filthy matters is not prohibited the decision in this particular case is apparently intended to meet the sentimental wishes of a particular community. The disposal of sewage is a difficult one in India altogether and "throw backs" of this kind must be very disheartening to the promoters.

The plague mortality throughout India is steadily rising. For the week ending March 5th 28,919 deaths were recorded, as against 27,858 for the previous seven days and 29,648 for the corresponding week of 1903. The disease is increasing in the United Provinces, the Punjab, Bengal, and the Central Provinces. The detailed figures are: Bombay Presidency, 6442 deaths; United Provinces, 6910; Punjab, 5550; Central Provinces, 2040; Bengal, 3305; Bombay city, 964; Calcutta, 174; Karachi, 81; Madras Presidency, 674; Mysore State, 388; Hyderabad State, 813; Central India, 756; Rajputana, 427; and Kashmir, 395.

There appears to be ten days' quarantine at Camaran Island for Indian Mahomedan pilgrims to Mecca, notwithstanding that these pilgrims have already spent 15 days on board and the ship is classed as "healthy." The Turkish Government is to be asked to modify these hardships and to exempt the pilgrims from further quarantine provided the ship be passed as "healthy." An important point is that these pilgrim ships do not touch any intervening ports.

A scheme is on foot to revive the Madras Nursing Institute. The supply of trained nurses is now so uncertain that something in this direction must be done. A conference of senior medical officials and private practitioners in Madras was recently held and it was resolved to found an institute with an English-trained matron-superintendent and several locally trained nurses under her from which nurses can be supplied to up-country stations at reasonable rates. Considering that some of the railways have their staff of trained nurses Madras must be very behindhand. I understand that the Bengal-Nagpur Railway has English-trained nurses for the officials on the various sections of its line and there is the organisation started by Lady Curzon for the better supply of trained nurses at other than hospital towns and in the chief up-country stations.

March 19th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Death of Councillor R. W. Haines, M.R.C.S. Eng., L.S.A.

I MUCH regret to have to chronicle the sudden death of Mr. R. W. Haines, a highly respected member of the medical profession whose genial personality will be much missed in Birmingham and particularly in Balsall Heath, a suburb which he has represented upon the city council ever since it has been included within the city boundaries. Mr. Haines, who was one of the oldest practitioners in the city, was born at Bromsgrove and educated at the school in that town. He pursued his medical studies at King's College, London, and after qualifying came to Birmingham some 36 years ago and settled down in Balsall Heath. He always took a deep interest in public affairs and was a member of the local board of Balsall Heath while that district was still separate from the city. About 12 years ago it became included within the boundaries and Mr. Haines was elected one of its representatives on the city council. He was made a member of the free libraries committee and for some time was its chairman. In the work of this committee he always displayed a deep interest and in fact attended a meeting of one of its subcommittees the day before his death. He was also a member of the lunatic asylums committee and for two years was chairman of the Winson Green subcommittee. At recent meetings of both the above committees and of the city council resolutions of sympathy and condolence have been passed. Mr. Haines, who was in his sixty-first year, was suddenly seized with an attack of angina pectoris to which he succumbed in three hours.

The Dean of Worcester and Vivisection.

In my last letter but one I mentioned that at a meeting of the local branch of the Society for the Prevention of Cruelty to Animals, of which he was president, the Dean of Worcester made some remarks in favour of vivisection which were not received with general satisfaction. As a consequence the Dean stated that if his views were not in harmony with those of the members of the branch he should resign his position in connexion with it. Since this letter it appears that so much adverse comment has been made that the Dean has carried out his threat and resigned the presidency of the branch. At a meeting of the Worcester Medical Society the following motion was passed:—

> This meeting has much pleasure in learning that the Dean of Worcester is able to distinguish between the experiments made on animals for scientific purposes and cruelty to animals and begs to congratulate him on his action in severing his connexion with the Worcester Society for the Prevention of Cruelty to Animals, which appears unable to do so.

The Dean has expressed his thanks for, and gratification at, the resolution above quoted and in his reply states that a paragraph in the society's report had led him to believe that it had no objection to vivisection when conducted properly. It is much to be regretted that a society which does, and has done, so much really valuable work should mix itself up with an antivivisectionist propaganda which cannot be approved of by its more thoughtful and better-informed supporters.

Care of the Feeble-minded.

For a number of years the Birmingham education authority, whether school board or city council, has taken much interest in the subject of the care of feeble-minded children and recently the matter has been very much pushed to the front by the energetic action of Mrs. Hume C. Pinsent who is chairman of the subcommittee of the education committee charged with the care of the schools frequented by these unhappy children. A conference of the after-care committees of this city and of Leicester and Nottingham has recently been held in Birmingham and a large number of representatives of boards of guardians and education committees were present. The Lord Mayor, in welcoming the members of the conference to the Council House, where the meeting was held, said that he was glad that Birmingham should have been chosen for a conference of such national importance. Hitherto this vast subject had only been in the hands of those who had seen the great danger to the community generally by allowing feeble-minded members of society to go about in an untrained condition. These unfortunate people often fell victims to the evil-minded. Now that the town councils had undertaken educational work he hoped this matter would receive their attention. He knew it would be a surprise to many when they were asked to provide for the permanent care of the feeble-minded. As a matter of fact, these were already being accommodated in special schools, but after being kept there at great expense to the age of 16 years they were allowed to go adrift, many to make their reappearance in crime. In this way they really cost the public more than if permanent control had been taken of them. In the absence of Miss Dendy, secretary of the Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded, a paper by that lady was read by Mrs. Pinsent. A child of low mental capacity but well trained, said the writer, would generally present a more favourable impression than one of higher intellect who had been neglected and thus it would be necessary for a careful medical examination to be made before admitting to a permanent home. In Manchester a school for the care of the mentally deficient had been established, but though of a voluntary nature it was in touch with the education authority. There was danger, she argued, in teaching children to earn their own living, for if they were allowed to go out into the world it increased the probability of their taking upon themselves the responsibilities of parenthood. This was one of the things to be guarded against, as the majority of feeble-minded cases were the result of some hereditary trouble. Unfortunately there was no power by which parents could be made to part with feeble-minded children and she contended that the Act of 1899 dealing with the control of imbeciles should be made compulsory instead of permissive. To her mind it was absolute cruelty to train children to the age of 16 years and then to turn them adrift to look out for themselves. What was necessary was that permanent residential homes should be provided. All they asked in connexion with the cost was that it should be borne equitably by the community instead of, as now, by only a section of it. Although there was little hope for the cure of the feeble-minded, if kept from danger they undoubtedly improved both mentally and morally, and being so safeguarded inflicted no hardship upon them. On behalf of the Birmingham education committee its chairman, Councillor G. H. Kenrick, welcomed the conference at its sitting in the afternoon. He urged them not to attempt to force legislation. In order to make legislation speedy it would be necessary to bring before the public such a multitude of facts that they would be convinced of its desirability and would not set up any hostile demonstration. Mr. W. H. Dickenson urged that the first care should be to stop the propagation of feeble-minded offspring. Dr. W. A. Potts, chairman of the Birmingham after-care sub-committee, described feeble-mindedness as a preventable disease and mentioned as the principal causes heredity, insufficient nourishment in childhood, criminal parentage, and chronic alcoholism of parents. Dr. S. H. Perry, alluding to the lack of nutrition in early life as a cause, contended that the municipality should supply sterilised milk as infants' food to poor people at less than cost price. A halfpenny rate, bringing in £6000, would provide for this and minimise the evil to a remarkable degree. A plea for better accommodation for non-pauper imbeciles was made by Mrs. Pinsent. She said that paupers were provided for and so should be the imbecile children of the working classes. Parents, to whom the idea of the workhouse was repulsive, would contribute towards the cost of maintaining their children. At the close of the conference resolutions were passed in favour of making compulsory the Elementary Education of Defective and Epileptic Children Act of 1899; that an inquiry should be held to consider the advisability of confining pauper and non-pauper imbeciles in suitable establishments on a different certificate from that now required; and that boards of guardians should receive 4*s.* per week for every harmless lunatic confined in homes provided by them to the satisfaction of the Local Government Board. The same subject was also brought before the recent meeting of the Birmingham Society for Promoting the Election of Women Guardians by Mrs. Pinsent, who strongly urged that the permanent care of the feeble-minded and epileptics should be in the hands of boards of guardians and not of city councils. I observe that Dr. Potts has been reading a paper on the same subject before the members of the Sanitary Institute in London. Dr. Potts detailed some facts learnt by him in Birmingham and stated that out of 46 cases on the list of his committee 18 were earning wages varying from 2*s.* to 12*s.* per week, the average wage per week being 7*s.* 1*d.*, so that these people were adding a really valuable sum to the weekly budget of the family. Ten out of these 18 were never likely to become permanently self-supporting and 23 out of the 46 cases should be segregated in a permanent home. Dr. Potts also stated that he had recently visited a number of charitable homes around Birmingham and examined 862 children. He found that 94 of these were so far mentally deficient as to require permanent care. Dr. Potts also stated that he had generally found that one or both of the parents of feeble minded children were drunken. He urged the necessity of preventing marriage among the feeble-minded.

April 4th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Hospital for Consumptives.

THE annual meeting of the friends and supporters of the Manchester Hospital for Consumption and Diseases of the Throat and Chest was held on March 23rd. The report told of increased work both at Bowdon, where the in-patients are treated, and at Hardman-street, where the out-patients attend. There was a deficit of £536 on the year's working. The Crossley Sanatorium at Delamere is not likely to be ready for patients till towards the end of the year. It may be remembered that Mr. W. J. Crossley is building this at a cost of between £70,000 and £80 000, but an endowment fund of £100,000 is needed for its maintenance, towards which £56,417 have been obtained. The chairman, Mr. W. J. Crossley, expressed his sorrow that consumption did not seem to be decreasing. It was estimated that there were 160,000 consumptives in the country and, so far as he knew, only about 60 sanatoriums, with about 2000 beds, and these almost entirely for rich people who could pay four or five guineas a week. He hoped county councils would quickly obtain and use powers for erecting sanatoriums, though he did not know that any had as yet done so. The Manchester Hospital had large numbers waiting for admission and while waiting their chances of recovery became less. He spoke of the danger of relapse when patients returned to "their old surroundings, the old infected dwellings, and suffered from want of food." Nearly 50 per cent. relapsed. Dr. J. Niven, medical officer of health, referred to the efforts of the corporation to prevent consumption by issuing instructions as to how to avoid the disease and by sending medical officers to visit the homes of the people. But in many of the wretched homes the instructions could not be carried out and the help of hospital treatment was necessary. He thought that the public, through the municipalities, should take up the question of providing hospital treatment for poor people.

Presentation of Address to Dr. A. Hodgkinson.

Before the close of the annual meeting of the friends of the Hospital for Consumptives a framed illuminated address was exhibited which the board of management and the medical board will present to Dr. A. Hodgkinson, the senior physician, on his retirement under the age limit rule. In association with the late Dr. Shepherd Fletcher he founded the hospital in 1875 and the address referred to his devoted services to the institution. The chairman said he would remain connected with the hospital as honorary consulting physician. Dr. Hodgkinson was unavoidably absent but the address will be formally presented by the chairman.

Manchester Infirmary Board.

Mr. W. Cobbett has been elected chairman of the infirmary board and there is no doubt that he will prove an efficient successor to the late Mr. John Thomson. He presided at the meeting of the board on March 28th, when it was reported that the plans of the proposed new infirmary buildings at Stanley Grove had been referred to the building committee with an instruction to ascertain to what extent economies can be effected. A resolution of sympathy with the relatives of the late Dr. F. Renaud was passed.

Exhuming a Body.

On March 26th an advertisement appeared in the Cheshire county newspapers of an unusual character. It was in the form of an apology from the Northwich burial board for removing a dead body from Lostock Gralam burial ground and undertaking to pay the costs of an action commenced in the King's Bench Division. It seems that there was a dispute with the Lostock burial trustees as to the position for a monument over the grave of the daughter of a parishioner. An order of exhumation was obtained from the Home Secretary. The burial board sent men "at the dead of night" who took the body from the grave and buried it again in the burial board's unconsecrated ground two miles away. This remarkable and most objectionable proceeding the board said was covered by the Home Office order but this was found to be an error. The diocesan authorities said that a faculty should have been obtained and that the Home Secretary had expressed personal regret that a licence was granted. This high-handed proceeding on the part of the burial board led to a writ being served on the board, which was followed by the board giving way, making a public apology, and settling the action commenced against it by paying the plaintiff's costs. One feels some regret that the members of the board instead of the all-suffering ratepayers have not to bear the expenses entailed. There is a strong feeling that graves should be respected as sacred even by burial boards.

The Levenshulme Anthrax Case.

Reverting to the case of anthrax which was mentioned in THE LANCET of March 12th, p. 760, it may be remembered that the farmer who sold the heifer left the infirmary while waiting to be conveyed to the Monsall Hospital. He went home and died in a day or two. The young man, Cresswell, who dressed the carcass for the Levenshulme butcher was taken ill and brought back from Sandbach and admitted to the Monsall Hospital, where he is said to be recovering. On March 22nd the butcher was summoned before the magistrates. The facts of the case were as follows. The heifer was on the farm of Pimlott, the owner, and on Feb. 23rd was observed to be ill. Next day some medicine was given to it but it did not improve and about mid-day Pimlott bled it to death when it was in a dying condition. Clarke, the butcher, sent Cresswell to dress it and he called Clarke's attention to the spleen which was enlarged. Notwithstanding this he bought the carcass, paying a low price. Professor S. Delépine certified Pimlott's case as one of anthrax and steps were taken to isolate the farm. The inspector ascertained from Clarke that the whole of the beast was sold except the tongue which was in pickle. The tongue, with other tongues and meat in contact with it, was seized and handed to Professor Delépine. His report was to the effect that he microscopically examined various parts of the seven tongues and found that one (numbered 691) was from an animal that had died from anthrax or had been killed in the last stage of the disease Anthrax bacilli were found still living and capable of rapid growth, were still virulent and capable of infecting animals. The defendant and his family, the solicitor stated, had partaken of the meat but neither they nor their customers, so far as was known, had suffered in the slightest degree. In answer to Mr. Yates, the stipendiary, Professor Delépine said there was usually no great danger from eating the flesh of an animal which had died from anthrax provided that the flesh was cooked. The danger arose when the flesh was not cooked before eating or was handled by persons with wounds on their hands. The defendant was fined £10 and costs and on the application of the prosecution £3 3*s* extra costs were allowed. It is clear that he was culpably careless but without putting him into that class it is to be feared that the race of slink butchers, whose business consists in dressing up diseased meat for sale, is by no means extinct.

April 5th.

WALES AND WESTERN COUNTIES NOTES.

(From our own Correspondents.)

"The Treherbert and District Medical Attendance Society."

Through the death of Mr. E. S. Warburton, who was surgeon to the Treherbert collieries in the Rhondda Valley, a vacancy has occurred in the position which he had held for many years and an alteration is to be made in the relations previously existing between the colliers and their medical officer. At all the collieries in the great Rhondda Valley the sum of 3*d.* in the £ is deducted from the colliers' wages by the managers and is paid over to the colliery surgeon who provides all the necessary medical assistance and pays the expenses of the practice, taking all the risk of the collieries working short time or being entirely closed, as many were during the five months' strike of 1898, when, as there was no money being earned by the men, there was no poundage for the surgeons, although there was no intermission in the medical attendance upon the colliers and their families. The Treherbert colliers have decided to give up this arrangement which has worked well for many years and have established the "Treherbert and District Medical Attendance Society," the object and rules of which follow very closely on the lines of a medical aid society and contain some of the objectionable features of the latter. It is proposed to appoint a "head doctor" at a salary of £450 per annum and one or more assistants at a salary of £200 per annum, each to pay his own rent and household expenses. The society will provide and pay for a groom, horse, and conveyance and will also provide and maintain surgeries and pay for all drugs and instruments required. The number of medical assistants is to be increased or reduced proportionately with the variation in the number of members in the society, but whether the "head doctor" or the society is to decide the need for additional assistance is not stated. Any person may become a member of the society who is employed in the collieries or other public industries in the district and who contributes to the funds 1¼ per cent. of his earnings, an amount, it will be observed, equal to the 3*d* in the £ formerly deducted in the colliery offices. Among the objectionable features already referred to is the admission to membership of the society of business and professional persons who contribute such a sum as may be determined by the committee but not less than 3*d.* weekly. No wage limit is fixed and the surgeon would not in any way benefit by increased contributions demanded from well-to do tradespeople or professional persons. The single contribution either from the colliers or other members, it should be stated, entitles not only the head of the household but also his dependents to medical and surgical attendance As it is not proposed that the colliers' contributions should be less than formerly it is difficult to understand what they are to gain by the alteration. They are promised that if the funds allow a nurses' institute shall be established and that the moneys of the society shall be applied for the medical benefit of the members in any form approved of by a general meeting. The president, treasurer, secretary, and three trustees of the society are to be paid for their services such remuneration as the committee, of which they are members, shall decide, and as it will no doubt be the duty of one of these officers to collect each month the contributions of the members it is obvious that the management expenses will not be small. One objection to the new scheme from the medical practitioners' point of view is that money contributed by the men expressly for medical attendance may be used to pay lay officials and, further, that the reputation of the surgeon may be used by the society to obtain increased monthly contributions from employés in private establishments or from business or professional persons; he may indeed be exploited by the society entirely for its own benefit The disadvantage to the colliers will be that they will not be able to secure the services, or at any rate the continued services, of surgeons with reputations equal to those of the gentlemen now practising in the Rhondda Valley. Most of these practitioners have been in the district for many years and they all have a distinct influence on the social life of the valley, but it is quite certain that there is not one of them who would have been satisfied for long with the exacting duties of a colliery practice on a yearly income of £450 in a district, moreover, where house rents are high and living is costly.

Prevention of Small-pox—Bristol Methods v. Leicester Methods.

At a meeting of the Bristol health committee held on March 17th during a discussion arising out of a communication received from the Imperial Vaccination League a member of the committee took occasion to compare the sanitary condition of Bristol with that of Leicester to the detriment of the former city and stated that Leicester was quite at the top of the tree as regards health. In January of last year this same gentleman persuaded the health committee to send through the town clerk a letter asking the Leicester authorities for details of their method of dealing with cases of small-pox. As at that time there were some 20 cases of the disease occurring weekly in Leicester the town clerk of that town no doubt thought he was being "chaffed" and made no response. The medical officer of health of Bristol (Dr. D. S. Davies) in a very exhaustive letter to the local newspapers has shown that however high Leicester may be in the sanitary scale Bristol is still higher if judged by certain standards. For example, in the ten years 1893-1902 the average yearly infantile mortality-rate in Bristol was 146 and in Leicester 191 and during the same period the average annual diarrhœa death-rate in Bristol was 0·67 per 1000 and in Leicester 1 53 per 1000. Dr Davies's comparison of the behaviour of small-pox in Bristol and in Leicester during the early months of 1903 is very striking He says: "In the first six months of 1903 small-pox was introduced into Bristol on 16 occasions—that is, on an average oftener than once every fortnight—but was kept under absolute control by common-sense methods which I need not detail and only caused three deaths. In Leicester during the same period under the operation of the 'Leicester method' small-pox assumed epidemic spread and caused more than 300 cases and 21 deaths—i.e., seven times as many deaths as in Bristol, although Leicester is a comparatively small town of 220,272 persons."

Cruelty to a Cow.

A cattle dealer was recently fined 40*s.* by the Neath magistrates for peculiarly gross cruelty to a cow. In order it is said that the cow might present a good udder in the market on the following day the dealer placed a rubber ring on each teat. A police constable found the animal groaning and evidently in great pain which was at once relieved upon the rings being removed and the milk drawn off.

Vagrancy in Glamorganshire.

The Bridgend board of guardians recently invited other boards in Glamorganshire to confer as to the best means of dealing with the increase of vagrancy in the county. A meeting of members of the boards was held on March 31st when a motion was passed urging the President of the Local Government Board to give speedy effect to his promise to hold an inquiry into the question of vagrancy, having regard especially to labour colonies and child vagrancy. A suggestion that a labour colony on the lines of the Salvation

Army colony in Essex should be established in the county met with some sympathy but no definite steps were taken in this direction.

Assaults upon Children.

The large number of young men in the colliery districts who lodge in the houses of their married fellow workmen no doubt partially accounts for the prevalence of offences against young children which is a deplorable feature of crime in Glamorganshire. At the last Cardiff Assizes Mr. Justice Walton in sentencing a youth to 18 years' penal servitude for brutally assaulting a little girl said: "If you had not been protected at all it seems to me that you, or any man guilty of such an offence, would be torn to pieces by his fellow creatures, but whilst the law does not allow the friends of those who are outraged in this manner to take their own revenge the law must inflict adequate punishment."

University College, Bristol.

An amateur performance of *The Schoolmistress* is announced to take place at the Victoria Rooms, Clifton, on April 29th and 30th. The performances, which will be under the direction of Dr. D. S Davies, are in aid of the funds to acquire an athletic ground for the students of University College, Bristol.

April 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dispensary Medical Officers.

At a meeting of the Banbridge board of guardians held on April 4th a letter was received from Mr. Robert Martin inclosing a list of dispensary tickets for the consideration of the board as the persons to whom they were issued were in no way entitled to the benefits of the Irish Medical Charities Acts. In one case the relatives of the recipient are rated occupiers to the amount of almost £30 and in another case the ticket holder occupies between four and five acres of land. The guardians cancelled two of the three tickets, holding the third over for further consideration.

Irish University Education and the Cork Queen's College.

The city of Cork grand jury, consisting of some of the most representative gentlemen of the city and county, unanimously adopted the following motion recently:—

> That we, the grand jurors of the City of Cork assembled at the Spring Assizes of 1904, are strongly of opinion that the intellectual and material interests of the city demand that Cork shall continue to be a university centre; that the more highly trained the intelligence of a community the better fitted that community is to participate in the adminis[illegible]

The foreman having read the resolution for the presiding judge, the Lord Chief Justice of Ireland, his lordship stated he could not accept the resolution as it was outside the sphere of his duties and in the course of his remarks said, "they all knew how much he appreciated the intellect of Cork and the general ability of the citizens of Cork." He also added that "he appreciated and, if he might say so, agreed with the abstract considerations that were involved in the resolution."

Death of Mr. Hamilton Ross, M.D. Edin.

I regret to announce the death of Dr. H Ross at his residence, Ballynacree House, Ballymoney. He was a county Antrim man, born in 1829, the youngest son of the late Mr. John Ross of Drumagrove, Clough, Co. Antrim. Educated at the Royal Academical Institution, Belfast, he proceeded to the University of Edinburgh, where in 1855 he graduated M.D. He was also M.R.C.S. Eng. In 1854 he entered the Indian Medical Service in which he rose to a high position, being in turn physician to the Maharajah of Travancore and head of the medical service of that State and afterwards inspector general of prisons in Burmah. He subsequently retired and lived near Ballymoney, Co. Antrim. He married the eldest daughter of the late Judge Cook and has left one son (Dr. J. R. H. Ross) and five daughters. His death is deeply regretted by a large circle of friends.

April 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Infant Life Protection in a Small French Commune.

AT the meeting of the Academy of Medicine which was held on March 15th an account was laid before the meeting dealing with a letter addressed to the Academy by M. Morel who is mayor of the commune of Villiers-le-Duc (Côte d'Or). M. Morel set out the results which he has obtained during a consecutive series of ten years in his commune by the application of a few simple measures for the protection of infant life. The result is that the infantile mortality which at the beginning of the nineteenth century was 29 per cent. has within the last ten years in the commune in question practically fallen to nothing. The means adopted are as follows. Every necessitous pregnant woman who notifies her pregnancy at the seventh month at the Mairie is helped by the commune which provides her with a midwife and, if need be, with a medical man. After her confinement she receives one franc a day for ten days if she remains in bed. Every woman who has the care of a child is obliged to possess a sterilising apparatus if she does not suckle the child herself. All infants must be inspected every fortnight either at home or at the Mairie. In case of any infant being taken ill the fact must be notified at the Mairie within 24 hours. Finally, every mother or foster-mother who can exhibit her nursling in good health at the end of one year is given two francs for every month during which she has had the child under care. It is much to be hoped that the example of M. Morel will be followed by the mayors of many other communes.

A New Parasite.

At the meeting of the Academy of Medicine held on March 22nd M. Laveran reminded the members that on Nov. 3rd, 1903, he had shown specimens of a new parasite discovered in the Indies in the spleens of those patients who were suffering from an ill-defined form of fever (*fièvre irrégulière*). M. Laveran and M. Mesnil had described this parasite under the name of piroplasma Donovani. Now an army surgeon in Tunisia, M. Cathoire, has just sent to M. Laveran some scrapings from the spleen of an infant aged seven months which contained an abundance of parasites exactly similar to the piroplasma Donovani. M. Cathoire, who made a post-mortem examination of the body seven hours after death, stated that the spleen was 12 centimetres long by six and a half centimetres in width—i.e., it was much hypertrophied. These scrapings when stained by Laveran's method (blue with oxide of silver, eosine, and tannin) showed the parasites as oval or round elements, generally single, measuring from 2µ to 3µ in diameter. The protoplasm stained very slightly but there could be seen in the interior of each element a principal karyosoma which was round and an accessory karyosoma which was either round or staff-shaped and which stained better than the principal karyosoma. These karyosomata were sometimes in a state of division and M. Cathoire found in the general circulation bodies very similar to those found in the spleen. M. Cathoire's discovery is of great interest and it is to be hoped that medical men practising in Algeria and Tunisia will keep a look-out for cases of this disease and will collect information about its frequency and its clinical manifestations. Parasitic elements analogous to the piroplasma Donovani have been described as existing in the "buttons" which are endemic in certain hot countries—e.g., Aleppo button—and research might well be made into the question of the relationship, if any, which may exist between these "buttons" and the general manifestation of the parasite which has been observed in the Indies and by M. Cathoire in Tunisia.

Statistics of the Pasteur Hospital.

At the meeting of the Hospitals Medical Society held on March 18th M. Martin communicated the following figures from the Pasteur Hospital. From Oct. 1st, 1900, to April 19th, 1903, there were 2000 patients treated at the hospital with 189 deaths, or a mortality of 9.45 per cent. Cases of small-pox numbered 524, with 96 deaths; of diphtheria 443, with 50 deaths; of measles 126, with two deaths; of scarlet fever 92, with two deaths; of erysipelas 163, with 11 deaths; of non-diphtheritic sore throat 163, with three deaths; of suppurating glands 20, with no deaths; of hydrophobia 7, with 7 deaths; of chicken-pox 55, with 1 death; and of other diseases 179, with 17 deaths. There were 192 patients who were either mothers of sick children or children of sick mothers and among these there were no deaths. Finally there were 26 patients treated with antirabic antitoxin as a preventive and seven treated with antidiphtheritic serum as a preventive, with no deaths in either series.

A Case of Poisoning.

The Correctional Tribunal of Havre has just given judgment in a case of homicide by imprudence for which a hospital physician and the hospital dispenser were prosecuted. A child, aged six years, was given an injection of cocaine of a strength of 1 in 50 instead of 1 in 500 and died within a few minutes. The physician was fined 200 francs with a stay of execution. The dispenser was acquitted. The court held that the medical man had been imprudent in not himself verifying the solution and in allowing the syringe to be got ready by a porter and that he alone was responsible. The dispenser received the benefit of the doubt for the prescription could not be found and so its exact text could not be put in evidence.

April 5th.

NEW YORK.

(From our own Correspondent.)

Diphtheria on a Naval Vessel.

A very instructive instance of diphtheria occurring on board a naval vessel and its destructive effects before its nature was recognised is reported. The ship was the United States cruiser *Buffalo* which arrived at New York in October, 1902. Without being disinfected she proceeded to the Norfolk navy yard where she received on board 450 landsmen for training, making with her regular crew a total ship's company of about 750 men. During her stay of 44 days at Norfolk 38 cases of epidemic catarrh were treated and five cases of sore-throat. She left for New York and thence sailed to the West Indies on Dec. 12th; meantime ten cases of sore-throat appeared. Subsequently other cases occurred with severe general symptoms and swelling of the cervical lymphatics. On Dec. 22nd two cases appeared which were evidently of a more malignant character, one of which was fatal. The vessel arrived at Pensacola on Dec. 30th, having had 42 cases of so-called tonsillitis and eight of diphtheria admitted to the sick list. 48 cases were transferred to the naval hospital where bacteriological examinations revealed the true nature of the disease. The ship then went to Port Royal and on Jan. 22nd, 1903, she was vacated and thoroughly disinfected. On Feb. 2nd 206 men returned to the ship, the others remaining in hospital, among whom the disease continued to appear. On Feb. 17th the services of a bacteriologist were secured and the isolation of all having bacilli in the throat was rigidly enforced. This practice put an end to the epidemic. The total number of cases was 137. It thus appears that for nearly three months epidemic diphtheria prevailed in this small community, during which time the preventive measures which are recognised as most efficient were not employed. The lesson which this event teaches is of general usefulness but its special application to the medical department of the navy must be fully appreciated.

Candidates for the Public Health and Marine Hospital Service.

Very great importance is now attached to the qualifications of candidates for the positions in this comparatively new department of the general Government. Formerly the service was confined chiefly to the care of sailors sick in the ports of the country, but the recent legislation which placed this service at the head of our national public health system has added the whole realm of public hygiene, national and international. These positions have therefore become of vastly greater importance in the public estimation and the greatest care is taken in the selection of the officers to fill these places. From the announcement of examinations about to be held it appears that candidates must be of a high grade of education and character as certified by competent authority. The immediate examination for the service is of the most rigid and exhaustive character, covering the field of primary education, medicine and surgery, and, finally, the whole scope of hygiene, municipal, State, national, and international. These positions are now regarded by the highest grade of medical graduates as well worthy of their ambition. The tenure of office is permanent. The rate of pay is as follows: assistant surgeons, $1600; passed assistant surgeons, $2000; surgeons, $2500; commutation at the rate of from $30 to $50. All grades above that of assistant surgeon rece longevity pay, 10 per cent. in addition to the regular sal for every five years of service up to 40 per cent. after years' service.

The National Legislative Council.

The organisation of a National Legislative Council by Americal Medical Association was designed to provide a c mission, representing the medical profession, that shall h supervision of all measures relating to the Army, Navy, a Public Health and Marine Hospital Service that come bef Congress. A meeting of this council has recently been h at Washington and a large number of measures were brou forward for its action. Some of the more important are general interest. An effort is being made by the Pu Health and Marine Hospital Service to increase the capac of its hygienic laboratory and an appropriation was secu to erect suitable buildings. These buildings have b erected and, moreover, the scope of laboratory w has been greatly extended by the addition of th new branches—viz, medical zoology, pharmacology, chemistry. The council approved of the necessary legislat to carry this scheme into effect. The council also appro of a measure for establishing a corps of dentists and organising a corps of trained nurses in the United St navy. The council took action to have the Public Hea and Marine Hospital Service empowered to prepare and maintain a standard of antitoxin for determining the stren of antidiphtheritic serum and recommended that a diphtheritic serum should be introduced into the Uni States Pharmacopœia and that the standard prepared the Public Health and Marine Hospital Service should made officinal.

The New Mount Sinai Hospital of New York.

The opening of this hospital for inspection by the publi the popular event of the day. Upwards of 25,000 pe passed through the buildings in the two days of exhibit Judging it both in detail and as a whole it is undoubte the most perfect hospital construction in this country. Jewish charities of this city are of the highest grade excellence in construction, maintenance, and managem But in the lavish expenditure of money, to secure perfec of detail in even the most minute and unimportant feat of construction work, the New Mount Sinai Hospital excels any similar institution among us. This hospital originally located at Madison-avenue and Sixty-eig street where it had a long and honourable career. new hospital is located at Fifth-avenue and One Hun and First-street and occupies a block having a large expo upon Central Park. The entire cost of the hospital is upw of $3,000,000. The general arrangement of the build gives a central administrative building, with its offices residential apartments for the staff of officers: on one is a building for surgical cases and on the other a buil for medical cases, each being constructed in detail for special purposes; the building on the park side is devote private patients and its elaborate finish excels any hot the city; on the Madison-avenue side is the dispens every part of which is adapted in structure and equipn for its special work. The house for the training schoo nurses, the children's wards, the operating rooms which numerous and for special purposes, the pathological dep ment, the mortuary with its exquisite chapel, and the kitc and laundry are all, without exception, models in const tion and equipment. It should be stated that this hosp though supported by private funds, is never lacking in means necessary for its full and constant operation.

A Reserve Army Medical Corps.

A plan of having a reserve army medical corps has perfected by the Surgeon-General and approved by Secretary of War and will become law. The princ feature of the Bill authorises the President to issue c missions as first lieutenants in such corps to such gradu of reputable schools of medicine, citizens of the Uni States, as shall from time to time, on examination to be scribed by the Secretary of War, be found physica mentally, and morally qualified to hold such commissi the persons so commissioned to constitute and to be know the medical reserve corps. In emergencies the Secretar War may order officers of the medical reserve corps to ac duty in such numbers as the public interests require and may continue such officers on such duty so long as their services are necessary. It is provided that an officer of this corps who is unwilling to serve shall not be required to do so. When on duty such officer has all the authority and the full pay of a regular medical officer of the same rank.

March 26th.

Obituary.

FRANK RENAUD, M.D. EDIN., M.R.C.S. ENG.

By the death of Dr. Frank Renaud Manchester has lost her oldest consultant. Born in London in 1819 of an old Huguenot family, he appears to have begun some preliminary medical studies in England but soon went to Edinburgh where he took his degree of M.D. in 1844 and in the same year became a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries. He at once settled in Manchester and in 1845 was elected one of the physicians to the Ardwick and Ancoats Dispensary which has now developed into the Ancoats Hospital with 114 beds for in-patients. In 1848 he was elected by the casting vote of the chairman one of the honorary physicians to the Royal Infirmary. In those days the physicians and surgeons were elected by the votes of the infirmary trustees—i.e., by the subscribers of three guineas a year—and the proceedings resembled those of a Parliamentary election. The polling took place at the infirmary. Each [illegible] carriages were in [illegible] conditions took pl[illegible] and Dr. H. Simpso[illegible] Shortly afterwards another vacancy for a physicianship occurred, when Dr. Morgan, being unopposed, had a walk over. Soon after his appointment at the infirmary Dr. Renaud became lecturer on medical jurisprudence at the Pine-street Medical School but subsequently exchanged this position for the chair of morbid anatomy and pathology which he occupied with distinction. The Pine street school in course of time became the medical faculty of the Owens College but before that time Dr. Renaud had relinquished his connexion with the medical school. His opinion was much valued by the public and by the members of his own profession and in addition to his busy consulting practice he became the consulting physician to various lunatic asylums. His connexion with the Manchester Royal Infirmary, in which institution he always took the most affectionate interest, was maintained unbroken from 1848 to 1903 as physician, consulting physician, and advisory member of the board, to which honourable and complimentary position he was elected by the board of management in 1892. He was a man of what is called a conservative mind, clinging somewhat to the old ways and not fond of change for the sake of change, and so during the long drawn-out controversy as to the removal and rebuilding of the infirmary he was the staunchest and most uncompromising advocate of its retention in Piccadilly. When therefore it was decided by the trustees that it should be rebuilt in Stanley-grove he resigned his seat on the board, together with the chairman and the majority of the members. But the respect in which he was held by those who agreed with, and by those who differed from, him was so great that it culminated in the presentation to the infirmary of his portrait in oils which now hangs in the board room of the institution which had been so long dear to him and to which he had given so much of his time, his sympathy, and his talents. The late Mr. John Thomson, the chairman of the new board, in accepting the portrait, said that Dr. Renaud "had endeared himself to all who knew him by his courtesy and kindness and nothing could exceed the interest he had taken in the Royal Infirmary. There was no one whose likeness had a greater right to a place in the centre of that institution." His interests were, however, not confined to his professional work. He had a strong literary bent and was an enthusiastic antiquarian. In 1876 he prepared for the Cheetham Society "Contributions towards a History of the Ancient Parish of Prestbury," much of which information was embodied by Mr. Earwaker in his "East Cheshire, Past and Present," and led to his election as a Fellow of the Society of Antiquaries. He contributed many papers to the Transactions of the Lancashire and Cheshire Antiquarian Society on its establishment in 1883. In 1885 he wrote under the auspices and authority of the Manchester Royal Infirmary a short history of the "House of Recovery" in Aytoun-street, the fever hospital connected with the infirmary. At one time, indeed, the fever cases were treated in wards in the upper storey of the infirmary itself. Now they are dealt with at the Monsall Hospital which has passed under the control of the corporation. Until near the close of his life his energy and tenacious vitality seemed to endow him with perpetual youth and though living for many years at Prestbury and then at Alderley Edge, he would till quite recently go to his consulting rooms in Manchester, more perhaps from habit than for the fees which it pleased him to think an "octogenarian physician," as he called himself, might chance to pick up, and he was present at the annual meeting of the infirmary trustees a few weeks ago. He married late in life a lady of one of the Cheshire county families, who died two or three years ago, and left no family. His funeral at Alderley was marked by many tokens of respect and regard by members of the infirmary board and medical staff and by representatives of many public bodies as well as by private friends.

JOSEPH PEEKE RICHARDS, M.R.C.S. ENG., L.S.A.

Mr. Joseph Peeke Richards, whose death occurred somewhat suddenly at Ealing on March 22nd, will be regretted by the many friends who knew and esteemed his sterling qualities of character. He was the son of a medical man and was educated at King's College, London, of which he was an Associate, taking his medical diplomas in 1863. After qualifying he became house surgeon to the Stockport Infirmary; his next post was that of assistant medical officer at the Devon County Asylum whence he was elected to a similar post at the Hanwell County Asylum under Dr. J. Murray Lindsay. On Dr. Lindsay's resignation Mr. Richards succeeded him in the office of medical superintendent of the female department. Mr. [illegible] ties of this office for upwards of [illegible] success and ability. His con- [illegible] and his methodical habits and keen judgment made him a very successful administrator of the large establishment committed to his charge. His thorough general knowledge of his profession and careful study of his cases, in addition to his personal sympathy with his patients, showed him to be a most capable alienist physician. The deceased gentleman, who was 63 years of age, has left a widow and family to deplore their bereavement.

Medical News.

UNIVERSITY OF ABERDEEN.—The following candidates have completed the first medical examination:—

Ernest E. Allaway, John Anderson, Douglas Walker Bruce, A. L. E. Coleman, William Y. Davidson, Thomas Donaldson, Norman A. Duncan, James William Littlejohn, W. J. Macintosh, Daniel J. McKinnon, James M Mathieson, Harry Middleton, Secossene Pissroux, Walter Richards Stephen, Alexander Stewart and William Lemmon Stewart.

The following have passed a portion of the first medical professional examination:—

William Stephen Angus, George Davidson, John Geddes, Herbert Hargreaves, James B. McAllan, William George McDonald, Elizabeth McHardy, Elizabeth M. McLaggan, Andrew James Shinnie, Alex. D. Trail, M. J. Williamson, and Charles Coutts Wood.

The following have completed the second medical professional examination:—

William Bain, *Robert Chalmers, George Cooper, *James George Co[illegible] *M[illegible] †J[illegible] Im[illegible] S[illegible] Mc[illegible] Mi[illegible] Ja[illegible] Stu[illegible] Cri[illegible]

The following have passed the first portion of the second medical professional examination:—

Henry Begg, William Begg, Theodore Chalmers, James McK. Clark, Stewart O. Howard, Eneas K. Mackenzie, William A. H. McKerron, and John Murray.

The following have completed the third medical professional examination:—

*Robert Brown, Hubert K W. H. Dornhorst, Robert R. Duncan, Richard Eager, George J. Forgie, William Low, *James B. McDiarmid, James McIntosh, James Mackenzie, Kenneth Mackinnon, George Milne, Harry Ross Neilson, Paul B Roth, Robert F. Russell, James Archibald B. Sim, Charles M. Smith, *Robert H. Spittal, John H. Stephen, J. F. B. de Villiers, and Lisette A. M. Wilson.

The following have passed the first portion of the third medical professional examination:—

Mary R. Bisset and William Ewan Reid.

The following have passed the final medical professional examination for M.B. and Ch.B under the new regulations:—

George Adam, Aberdeen; Francis Anderson, Gamrie; William Beedie, Gamrie; †James Clark, Sorn, Ayrshire; Alexander Dyce Davidson, Aberdeen; Francis W. Davidson, Brompton, London; Alexander Duguid, Aberdeen; James Farquhar, Aberdeen; Alexander Flett, Findochty; Archer I. Fortescue, Aberdeen; James Alexander Gibb, Udny; James S. Gray; J. D. Henderson, Aberdeen; John Hunter, Aberdeen; Alexander Hutchison, Aberdeen; Herbert M. Jamieson, Aberdeen; F. Hernaman Johnston, Aberdeen; Neil Kennedy; William W. J. Lawson, Aberdeen; Donald McKay, Dufftown; Malcolm Macleod, Balallan, Stornoway; Charles G. MacMahon, Aberdeen; William M. McPherson, Newburgh; Alexander McRobbie, Aberdeen; Archibald D. Pringle, Aberdeen; James Robertson, Aberdeen; Alexander Nicolas Ross, Balintore, Ross shire; B. R. G. Russell, The Manse Walls, Orkney; Herbert W. B Ruxton, Balmacassie, Ellon; William Alexander Smith, Hatton, Cruden; and *William Wood, Peterhead.

M.B. and C.M. (Old Regulations).—Alexander S. Cardno.

* Passed with distinction. † Passed with much distinction.

Royal College of Surgeons in Ireland.—The following is the list of prizes awarded for the winter session, 1903-04:—Descriptive Anatomy: Junior: D. P. Clement, first prize (£2) and medal; and G. S. Levis, second prize (£1) and certificate. Senior: D. Adams, first prize (£2) and medal; and P. G. M. Elvery, second prize (£1) and certificate. Practical Anatomy: First year: G S. Levis, first prize (£2) and medal; and D. P. Clement, second prize (£1) and certificate. Second year. P. G. M. Elvery, first prize (£2) and medal; and T. A. Buchanan, second prize (£1) and certificate. Practice of Medicine: R Bury, first prize (£2) and medal; and P. D. Sullivan, second prize (£1) and certificate Surgery: J. S. Dunne, first prize (£2) and medal; and R. Bury and F. Lyburn (equal), second prize (£1) and certificate. Midwifery: J S Dunne, first prize (£2) and medal; and R. A. Brown, second prize (£1) and certificate. Physiology: D. Adams, first prize (£2) and medal; and T. Sheehy, second prize (£1) and certificate. Chemistry: D. P. Clement, first prize (£2) and medal; and A. E. S. Martin, second prize (£1) and certificate. Pathology: L. Lucas, first prize (£2) and medal; and P. D. Sullivan, second prize (£1) and certificate. Physics: A. E. S. Martin, first prize (£2) and medal; and W. G. Ridgway, second prize (£1) and certificate.—The lectures and practical courses of the summer session will commence on Monday, April 11th.

University of Oxford: Second Examination for the Degree of B M. and B.Ch.—The Board of Faculty of Medicine gives notice of the following changes in its regulations (see Examination Statutes, pp. 190, 191). The regulations under the heads of medicine, surgery, midwifery, and pathology have been amended and now stand as follows. V. Medicine.—The examination shall be held in the principles and practice of medicine and shall consist of the following parts: 1. A written paper of three hours. 2. Clinical work. This shall include (*a*) a full clinical report upon a given case, together with a statement of the treatment, and the writing of appropriate prescriptions; and (*b*) an oral examination upon other cases selected by the examiners. 3. Practical examination in the chemical and microscopical methods of diagnosis, such as the investigation of urine, identification of parasites, examination of blood, sputum, &c., and on the use of special instruments for diagnostic purposes. 4. A *vivâ voce* examination. VI. Surgery.—The examination shall be held in the principles and practice of surgery. (Candidates will be expected to possess a general knowledge of the surgery of the eye and ear). The examination shall consist of the following parts: 1. A written paper of three hours. 2 Clinical work, partly in writing, partly oral. 3. An examination in surgical anatomy, the methods of operations, questioning on the living or dead subject, and the use of surgical instruments and appliances. 4. A *vivâ voce* examination. VII. Midwifery.—As at present, except that the words "(1) paper work, (2) practical examination ......" have been replaced by the words "(1) a written paper of three hours; (2) a practical and *vivâ voce* examination. ......" In the *vivâ-voce* examination in medicine, surgery, and midwifery candidates shall be shown pathological specimens and shall be examined upon such appearances as bear upon the clinical aspects of disease. VIII. Pathology (including General Pathology, Morbid Histology, and Bacteriology).—The examination shall consist of three parts: (1) a written paper of three hours; (2) a practical examination of three hours; and (3) a *vivâ-voce* examination. These regulations will come into force at once and take effect at the examinations of Trinity Term, 1904.

Health of Gloucester.—The medical officer of health of Gloucester reports that during 1903 the death-rate of that city was 12·1 per 1000, being the lowest on record. The zymotic death-rate was 0·76 per 1000. The birth-rate was 28·2 per 1000.

Bristol Eye Dispensary.—The annual meeting of the subscribers to this institution was held on March 29th under the presidency of Mr. P. J. Worsley. The medical report stated that 2268 patients had been treated, being an increase of 444 as compared with 1902. During the year a large out-patient room and a waiting room had been added to the building. The financial statement was satisfactory and showed a favourable balance of £47.

The County Council Elections in the West of England and Wales.—To the names published in The Lancet of March 12th, on p. 760, must be now added those of Mr. John Beddoe, M.D., LL D. Edin., B.A, F.R.C.P. Lond., F.R.S., for the Bradford-on-Avon district of the Wiltshire county council; Mr. Mervyn Seppings Wilson, B.A. Cantab., M.R C.S. Eng., L S A, for the Chippenham district of the Wiltshire county council; Mr. Ptolemy A. Colmer, M R.C.S. Eng., L.R C.P. Lond., L.S.A., for the Yeovil borough of the Somersetshire county council; Mr. T. S. Hawkesford Hincks, M.D, C.M. Edin., J.P, for the Hay division of the Brecknockshire county council; whilst Mr. J. James, M.R.C.S. Eng., L.R.C.P. Lond., and Dr. Evans have been elected for the Taliesin and Nantcwnlle districts respectively of the Cardiganshire county council.

The Public House Trust.—The third annual report of the executive committee of the Central Public House Trust Association, of which Lord Grey is President, has just been issued and forms a pamphlet of some 200 pages, containing complete information relating to the 42 existing trust companies. The association was formed in 1901 with two objects: (1) to convert, wherever possible, the public-house from a drinking bar into a house of refreshment for the supply of wholesome food and non-alcoholic liquors as well as of beer and spirits; and (2) to provide such an organisation as will enable the licensing authorities to secure that all new licences with their high monopoly values shall be administered as a trust in the interests of the public and not by private individuals for their personal gain. According to the report, "the fear expressed in some quarters that trust management might tend to increase the national consumption of drink is shown to be unwarranted by facts, and evidence is given of the influence exercised in favour of the higher temperance by properly conducted trust houses."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Drought, Percy J., L.R.C.S.I., L.K.Q.C.P.I., L.M., has been appointed Divisional Surgeon to the Police of J Division, stationed at Barkingside.

Griffith, W. S., M B., C.M Edin., has been appointed Certifying Surgeon under the Factory Act for the Milford Haven District of the county of Pembroke.

Hogg, Gustave H., M.D Edin., has been appointed Port Health Officer for Launceston, Tasmania.

James, Walter T., M.B., Ch.B. Edin., has been appointed Second Assistant Medical Officer to the Joint Counties Asylum, Carmarthen.

Jeffares, J., L.R.C.P., L R.C.S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory Act for the Kegworth District of the county of Leicester.

Jones, Herbert, L R.C.S. Irel., D.P.H, has been appointed Honorary Bacteriologist to the Herefordshire General Hospital, Hereford.

Mackinnon, Charles, M.A., M.B., C.M. Glasg., has been re-appointed Medical Officer for the South District by the Cirencester Board of Guardians.

PARKER, CHARLES, M.B., C.M. Edin., has been appointed Honorary Medical Officer of the General Hospital, Launceston, Tasmania.

SPROTT, GREGORY, M D Glasg , has been appointed Port Health Officer for Hobart Tasmania.

STUMBLES, H. M., M B., B S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Amble District of the county of Northumberland.

THOMAS, JOHN LEWIS, M.R C.S , L S.A., has been appointed Medical

BRO[illegible] Sanatorium, Robert Major [illegible] 44 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE OLD LOVE AND THE NEW.

WE have received a copy of the *Christian Science Journal* for November, 1903, which contains "an experience of one who practised medicine for 12 years and then came to Christian Science." The gentleman who communicates the story of his conversion from scientific medicine to Christian Science appears to have founded his change of tenets upon the fact that a child of his, having shown symptoms of hip disease, and having spent many months in the open air at "what is considered one of the most bracing seaside places in England," became better about the time when help was sought from Christian Science. We feel that a man with a mind so superior to all logic as to be able to argue in this manner must be terribly cramped by the common-sense definitions and limitations of medicine. For we observe that he has *ceased to practise* The causal relations of common events as revealed to trained intelligence by hard work could mean nothing to so soaring a spirit, and it is well that Mr. W. F. W. Wilding has ceased to practise medicine. But ought he to wear the favours of the old love while professing his affection for the new? Mr. Wilding signs his communication, "M.R C.S., L.R.C.P."

"THE FILTHIEST TOWN ON EARTH."

IN the *Times* of April 6th a special correspondent gives a graphic account of the Chumbi Valley and he describes the town of Phari as the filthiest town on earth. The sod-built hovels of one storey, or at most two storeys, high prop each other up. A blue haze from the dried yak dung fuel fills the rooms which are permanently covered with a layer of soot. Water is almost non existent except during the melting of the snow. The only access for light and air is a square hole in the flat roofs "In the best quarter of the town, that in which the houses are two-storeyed, the heaped up filth—dejecta and rejecta alike—rises to the first floor windows, and a hole in the mess has to be kept open for access to the door. .. .. In the middle of the street, between the two banks of filth and offal, runs a stinking channel which thaws daily. In it horns and skulls and bones of every beast eaten or not eaten by the Thibetans lie till the dogs and ravens have picked them clean enough to be used in the mortared walls and thresholds. .. ... Here and there a stagnant pool of filth has partially defied the warmth and carrion, verminous rags, and bones are set round it in the broken yellowish ice. ..... A curdled and filthy torrent flows through the market place and half breed yaks shove the sore eyed and mouth ulcered children aside to drink at it" The men and women never wash themselves. The extreme cold and the fact that the diminished atmospheric pressure at the altitude at which Phari is situated causes breathlessness and apathy to follow on the slightest physical exertion are, no doubt, contributing causes to this almost incredible condition of human existence.

TREATMENT OF FLAT FOOT.

WRITING on this subject in the February number of the *Birmingham Medical Review* Mr. Leonard Gamgee says that the primary cause of the ordinary or static form of flat foot lies, not in the foot itself, but in the muscles of the calf of the leg. The three chief muscles concerned are the tibialis posticus, the flexor longus hallucis, and the peroneus longus. The first of these, after passing round the back of the internal malleolus, passes under, and gives support to, the inferior calcaneo-scaphoid ligament, thus aiding that ligament in keeping in position the head of the astragalus, which is the keystone of the longitudinal arch of the foot. The flexor longus hallucis tendon forms the tie rod to the longitudinal arch; while the peroneus longus tendon, in crossing the sole of the foot from without inwards, is one of the chief forces maintaining the *transverse* arch. Weakness of these muscles lessens the support given by them to the arches of the foot and the whole stress of maintaining the arches is thrown upon the ligaments, which stretch, and so the condition of flat foot is caused. The calf muscles will nearly always be found to be weak, soft, and flabby and the treatment to be relied upon chiefly is that directed towards the restoration of tone and strength to these muscles. The patient should regularly, twice or three times a day, carry out the following exercises, the shoes, of course, having been removed. 1. With the toes turned in the patient raises himself on to tip-toe and then lets the heels drop to the ground again. This should be done quickly and repeated until the muscles of the leg feel tired. The turning in of the toes is essential to its success. 2. The patient, standing, should raise the inner border of the foot from the ground till the foot rests on its outer edge. The sole is then brought flat on to the ground again. This also should be done sharply and repeated a number of times. 3. The patient, sitting with the knees crossed, circumducts the foot from without inwards, sweeping the toes round as wide a circle as possible. At first the patient finds it possible to continue these exercises for only a few minutes, but the time can generally be lengthened as the muscles become stronger. Combined with the exercise, massage to the foot and leg should be done daily and the patient [illegible] to take a moderate amount of walking ex[illegible] standing. In incipient cases these [illegible] sufficient without recourse being had to any artificial support to the arch in the form of pads or metal soles; but in more severe cases a metal instep arch, properly fitted to the boot, is useful, while in still more severe cases the boot invented by H. O. Thomas is most serviceable, as it both gives support to the arch and corrects the tendency to valgus. When there is marked valgus, treatment by exercises and supports should not be commenced till the valgus has been overcome. This may be done in one of two ways: 1. By tenotomy of the peronei tendons. This certainly overcomes the valgus but it tends to cause flattening of the transverse arch and so is not, in Mr. Gamgee's opinion, to be recommended. 2. Under an anæsthetic steady traction is made on the foot in an inward direction. The peronei muscles can be felt to yield, the valgus disappears, and the foot can be brought into a position of slight varus. At the same time the arch can to a large extent be restored. In this position the foot is fixed in a plaster case, extending from the balls of the toes to just below the knee. The plaster case should be kept on for from three to six weeks; and on its removal treatment by exercises and massage as above described *must* be regularly persevered in and a Thomas's boot must, for some time at all events, be worn.

DR. J. T. C. CONRY'S DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—I thank you for the insertion of my letter in your issue of March 26th, 1904, and also for the annotation. My co-signatories have nominated Mr. Walter L. Roberts of 79, Cambridge-gardens, North Kensington, to act with me in the matter, and Mr. E. Canny Ryall of 30, Harley-street, W., and Mr. Albert Stephen Hayman of 45, Welbeck-street, Cavendish-square, W., have most kindly volunteered their advice and assistance and have expressed their willingness to receive subscriptions. We shall feel indebted to you if you will publish in your columns a list of contributions. The list of those who have subscribed up to this date is given below. I am, Sirs, yours faithfully,

EDWIN T. ENSOR.

162, Ladbroke-grove, North Kensington, W., April 5th, 1904.

AN IMMENSE TRACT OF LAND WITHOUT MEDICAL MEN.

THE *Eastern Review* (Russian) says of the unsatisfactory state of affairs from the medical point of view in the Verchoyansk district, which is more than twice the size of France, that there are only one medical man, one accoucheur, and three field medical officers, of whom one lives at Zuluna, 1000 versts from the town of Verchoyansk, and two belong to the Verchoyansk syphilis infirmary, attached to which is a dispensary where the most necessary medicines are simply not stocked. The medical staff was changed lately but without improvement in the situation. The only patients received into the infirmary were those who could work. To the patients the ultimatum was recently presented, work or leave, and nearly all left—and it was winter.

NOTE ON THE VALUE OF GARLIC AS A TREATMENT FOR TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—Dr. Giulio Cavazzani's able article on the action of garlic as a prophylactic in cases of tuberculous infection, which appeared in THE LANCET of Jan. 9th, p. 90, and a further communication on the same subject by Dr. W. C. Minchin of Kells in *your issue* of Feb. 13th, p. 481, draw attention to a subject worthy of the closest consideration by medical men and experimental investigation by pathologists.

For some years past, as opportunity presented itself, I have been working out the influence exerted by garlic on such different forms of tuberculosis as have presented themselves for treatment in the military hospitals to which I have been attached. The garlic treatment was first brought to my notice owing to a relative of mine becoming infected with tuberculosis of the lungs whose sputum at the time swarmed with Koch's bacilli; this patient had a cavity in the left apex of the size of a walnut and also several consolidated patches in the lower lobe. He has been under continuous treatment with garlic for the past three years and has had his disease undoubtedly arrested as has been proved by repeated physical and bacteriological examinations. The treatment carried out by Dr. Minchin in his case I have adopted in my own cases in the army and have met with unqualified success, in so far that the disease has been temporarily arrested in all early cases and in several chronic fibroid cases which I have seen in consultation in private practice. I do not claim that each case has been cured, as tuberculosis of the lung may apparently appear cured while in [illegible] country, and were it not for the arduous strain of military [illegible] might have resumed their previous occupation in this country. I have also tried the external application of garlic crushed in a [illegible] applied as a poultice to tuberculous ulcers with most [illegible] results and strongly recommend its trial. It has a powerful germicidal action and when mixed with powdered [illegible] the power of cleansing and healing the most [illegible] On my arrival in India I was much interested to find garlic was used by the natives of this country and that it [illegible] been used for generations pa[illegible] for all forms of skin disease, [illegible] purating sores. They apply it [illegible] wood ash, and leave it on o[illegible] tion occurs. They also use it i[illegible] of dyspepsia and gastric catarrh and I am informed with [illegible] may add that in my cases of tuberculosis of the lungs I have [illegible] the expressed juice of the fresh plant mixed with a little water in [illegible] or two drachm doses taken before bed-time and first thing [illegible] morning internally, to have given the best results, and in bad cases [illegible] have used the expressed juice of the fresh plant alone (without [illegible] tion) on a sponge in a zinc inhaler (Burney Yeo's pattern) at [illegible] and also at intervals during the daytime, as well as [illegible] administration of the diluted juice. In no case have I found [illegible] when taken internally, to affect digestion, and after the first [illegible] my patients did not object to it, [illegible] improved their appetites and relieved [illegible]

I am, Sirs, yours faith[illegible]

E. BLAKE KNOX, M.D. Dub.,

Captain Royal Army Medical Corps, late Assistant [illegible]
Pathology and Bacteriology, Trinity College, [illegible]

Simla, March 8th, 1904.

THE MORPHIA HABIT.

To the Editors of THE LANCET.

SIRS,—Can any reader of THE LANCET recommend from [illegible] knowledge a comfortable and well-managed [illegible] England where the morphia habit is successfully treated? [illegible] no object. Bracing air, good cuisine, and plenty of [illegible] essential. I am, Sirs, yours faithfully,

[illegible] J.

March 31st, 1904.

CHLORIDE OF ZINC IN GONORRHŒA.

SURGEON writes: "Can any reader kindly name any book [illegible] as to the use of chloride of [illegible] other information the fol[illegible] for its use? Should it be [illegible] gnosed? What stre[illegible]h [illegible] how long to be ret[illegible]d in urethra each time, and should it [illegible] time of injectio[illegible] [illegible]ly long time to the external mucou[illegible] strength of the lotion varied? If so, [illegible] and the indications for discontinuing [illegible] or weeks is it usually applied?"

◆

M.B. will not find Dr. Maudsley's well-known book to [illegible] information which he seeks. The Transactions of the [illegible] Research Society, Modern Spiritualism, a History and a [illegible] by Mr. F. Podmore, the work by the late F. W. H. Myers [illegible] Personality after Death, the late Dr. F. G. Lee's book "[illegible] the Unseen," and Mrs. Crowe's "Night Side of Nature" migh[illegible] consulted.

Research is working at the subject of the reducing [illegible] creatinine and uric acid on Fehling's solution and would [illegible] to know of any works of reference dealing with it.

M.D.—The address of the British Syphon Manufacturing [illegible] 2, Gresham-buildings, Basinghall-street, E.C. The works [illegible] Barnsbury, N.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, [illegible] addresses of [illegible]

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

During the week marked copies of the following newspapers have been received: *Reading Mercury and Oxford Gazette, Liverpool Daily Post, Scotsman, Aberdeen Free Press, Aberdeen Free Press (Weekly), Buxton Advertiser, Boston Independent, Westminster Gazette, Hertfordshire Mercury, Literary Digest (New York), Windsor and Eton Express, Standard, Cardiff News, South Wales Daily News, Surrey Advertiser, Coventry Herald, Birmingham Daily Mail, Mining Journal, Local Government Chronicle, Ipswich Times, &c.*

Communications, Letters, &c., have been received from—

The Arris and Gale Lectures
ON
THE NEUROLOGY OF VISION.

Delivered before the Royal College of Surgeons of England on March 16th and 18th, 1904,

BY J. HERBERT PARSONS, B.S., D.Sc. LOND., F.R.C.S. ENG.,

CURATOR, ROYAL LONDON OPHTHALMIC HOSPITAL; LECTURER ON PHYSIOLOGICAL OPTICS, UNIVERSITY COLLEGE, LONDON.

LECTURE I.

Delivered on March 16th.

THE AFFERENT VISUAL PATHS.

MR. PRESIDENT AND GENTLEMEN,—The nerves which deal with the special senses are specially differentiated sensory nerves. In the process of differentiation, however, the analogies which they present to the ordinary spinal sensory nerves are greatly obscured and may be easily overlooked. Just as the segmental arrangement of the central nervous system is most manifest in the cord, becomes obscured in the medulla oblongata, and is scarcely appreciable in the higher parts of the brain, so the cranial nerves assume that increased complexity which is characteristic of the evolutionary process wherever it occurs. Considering first the mechanism of transmission and transmutation of an ordinary sensory impulse we find that the physical stimulus is received by an end organ and is there transformed into a nervous impulse. This is carried by a nerve fibre along the sensory nerve and the dorsal spinal root to the cord. It travels up in the posterior columns of the cord to the nucleus gracilis or the nucleus cuneatus as the case may be. The whole of this course is along the processes of a single cell or neuron, which has been called the neuron of the first order. The impulse is taken up in the nucleus gracilis or nucleus cuneatus by a second cell and is carried along the nucleo-thalamic tract or mesial fillet to the opposite optic thalamus; other fibres, especially those derived from the nucleus cuneatus, pass to the superior colliculus or corpus quadrigeminum. These cells in the nuclei gracilis and cuneatus are the neurons of the second order. A third cell, the neuron of the third order, situated in the thalamus or colliculus, carries on the impulse to the cortex cerebri. Here the nervous impulse is transformed into a psychic

pical.

the impulse in some physical
e are aware, no preparation of
fall upon the sentient surface.
rves with the exception of the
xtent, the auditory nerve. In
the former case, with which we are immediately concerned, the whole eye, with the exception of the retina, is a complicated mechanism for preparing the physical force, light, so that it may produce specific and complex sensations. It is well, therefore, to emphasise the fact that in dealing with visual sensations the stimuli themselves are composite, and for all we know each component may be provided with its own transmitting apparatus.

At the outset of our comparison of the anatomical structures for the transmission of visual and common sensations we are met with difficulty. The so called optic nerve is in no sense comparable with an ordinary sensory nerve. Morphologically and physiologically it is part of the brain. Careful investigation shows that the true optic nerve, corresponding with the sensory neuron of the first order, must be sought in the retina itself. Even so the analogy is not absolutely complete, for the dorsal root ganglion cell, which forms the first neuron, emigrates at an early stage of development from the neural crest and loses its connexion with the cord only to regain it at a later stage. The retina, on the other hand, develops entirely in the invaginated primary optic vesicle.

The morphology of the rods and cones.—If we seek the analogues of the successive sensory neurons in the optic system we are met with further difficulties. Histological investigations of the retina have shown that the conducting elements may be divided into three orders: (1) the rods and cones, with their nuclei, which form the main mass of the outer nuclear layer, and their processes which contribute to the outer reticular layer; (2) the rod and cone bipolars, which form the main mass of the inner nuclear layer with their axons, which contribute to the inner reticular layer; and (3) the ganglion cells, the axons of which form the nerve fibre layer, and the main mass of the so called optic nerve. We shall see later that the ganglion cells and their processes behave exactly like the second order of sensory neurons, a fact which affords further evidence that the optic nerve belongs essentially to the central nervous system. The neurons of the first order therefore must be either the rods and cones or the bipolars. In the former case an extra neuron is intercalated in the visual afferent path; in the latter no such assumption is necessary, but it remains to explain the nature of the rods and cones. There can be no doubt that the second view is the simpler and more probable. If we adopt it the rods and cones will be epithelial ependymal cells corresponding with Merkel's *Tastzellen* or touch cells and the epithelial cells of end organs, with the neuro-epithelial cells of taste-buds, the epithelium of the organ of Corti, &c. The olfactory nerve will prove the sole exception to such a scheme, the sensory neurons of the first order being here situated actually upon the surface like the sensory cells of some invertebrata.

If we consider the position of the retinal pigment epithelium and the rods and cones from an embryological standpoint it will be seen that they correspond with the lining of the primary optic vesicle—i.e., with a part of the central neural canal. This is itself an invagination from the surface epiblast, and its lining epithelium therefore will correspond with the superficial epithelium of the body. In the neural canal these cells become ciliated ependymal cells, so that their condition in the retina is merely a specific differentiation. Evidence in favour of the ependymal nature of the rods and cones has been brought forward by Krause. This tends to show that the outer limbs are really coiled up cilia. Verhoeff, working with me in the laboratory at Moorfields, supports and extends this theory by further observations. If the rods and cones are ependymal cells we might reasonably expect to find the pigment epithelium also showing traces of the same origin. By bleaching and special staining methods—e.g., Mallory's phosphotungstic acid hæmatoxylin—a membrane, resembling the external limiting membrane, can be made out surrounding the internal ends of the pigmented epithelial cells. The appearance in transverse sections is that of a delicate line running along near the inner margins of the cells. The latter project beyond it in the form of processes of variable length, showing that the line does not represent the inner contour of the cells. Black dots occur at regular intervals along the line, each occurring at the line of junction of two cells. On careful focussing it can be seen that the line is not always at the same level, evidently passing sometimes behind and sometimes in front of the cells. Hence it is difficult to photograph the membrane. In oblique sections the true structure is made more apparent, the membrane appearing not as a straight line but as a series of hexagonal loops which are fused together at the lines of contact so as to form a screen into the openings of which the pigment cells project. The little dots are the points of junction of the loops—i.e., the sections of the lines of contact.

The following considerations are in favour of this structure being a true fenestrated membrane. In the first place, it does not correspond in position with the margins of the cells; secondly, with phosphotungstic acid hæmatoxylin followed by acid fuchsin it stains blue, whereas the cells stain pink or not at all and show no vertical blue lines between them; thirdly, in certain places where two neighbouring cells have shrunken apart it remains intact; fourthly, it can be frequently seen projecting beyond a fragmented part of the pigment layer; and, fifthly horizontal hexagonal loops may sometimes be seen even in unbleached specimens, the cells having fallen out. The membrane is not simply the cement substance or neurokeratin envelope which lies between the cells. This does not stain by the methods used, but on careful focussing a bright line or space can be made out between the cells. Staining reactions tend to show that

No. 4207.

Usher and Dean suggest that fat may be removed from the degenerated nerve and carried by lymphatics and deposited in the opposite nerve. This is disproved by its absence in other parts of the nervous system, in spite of the innumerable researches carried out by the Marchi method. We are forced to conclude that the degeneration is a genuine one and, if so, what is the nature of the fibres involved? It is not probable, as Usher and Dean point out, that they are concerned in the pupillary reflexes, as these remain absolutely unimpaired. They must belong to some form of inter-retinal fibres—a reversion, in a sense, to the much-disputed inter retinal tract (commissura arcuata anterior of Hannover, vordere Bogencommissur of Stilling). Ramon y Cajal has demonstrated by the methylene blue method in rabbits a division of the optic fibres and Kölliker discovered an isolated example in a human fœtus. Bernheimer was struck by the variety in size of the fibres in the chiasma, so that it appears in many places as if the larger fibres divided. It is not improbable that the degenerated fibres in the nerve of the uninjured side are collaterals and that they may be distributed to physiologically corresponding parts of the opposite retina, possibly inducing chemical changes in the visual substances or movements in the cells and so afferent impulses which subserve a modified type of binocular vision. These fibres would therefore be centrifugal fibres. That fibres which are undoubtedly centrifugal occur in the optic tracts and nerves was first proved by the Golgi method by Ramon y Cajal and has been confirmed since by other methods (van Gehuchten, Held, Kölliker, and von Monakow) They arise in the external geniculate body, the superior colliculus, and probably in the pulvinar of the optic thalamus. They end by arborisation in the inner reticular layer. Their functions can only be conjectured and are possibly those already suggested for the inter-retinal collaterals. In all of my experiments there was some degeneration in both tracts. This may be explained partly by the diffuse injury which probably always results from the lesion and which is manifested by diffuse degeneration in the nerve. I do not think that this accounts for it entirely. There are apparently more fibres degenerated in the tracts than in the nerve and we are here more powerfully forced to the conclusion that division of the fibres occurs. Most of the experiments were temporal lesions, with a view of obtaining, if possible, a pure degeneration in the homolateral tract. In these cases the degeneration in the contralateral tract usually showed smaller black globules, as if less myelin was present. Probably these were finer fibres—in fact, collaterals.

The basal visual centres and the neurons of the third order.—The optic tract runs round the cerebral peduncle and divides posteriorly into two branches—a lateral and a mesial. The lateral root contains the visual fibres and ends in the lateral geniculate body; the mesial joins the mesial geniculate body and consists of fibres which are not connected with vision.

The lateral geniculate body, in which the great majority of the visual fibres end in man, consists of alternating layers of white and grey matter. The grey matter contains the cell bodies and dendrons of the optic neurons of the third order. The white matter consists of the axons of the neurons of the second and third orders—i.e., the ends of the fibres from the optic tract and the beginnings of the fibres from the geniculate body to the cortex cerebri. The latter pass out laterally into an area situated on the outer side of the external geniculate body, known as Wernicke's field. Here they are joined by similar fibres from the superior colliculus and pulvinar, the latter being ventral to those derived from the geniculate body. They all turn round the caudate nucleus and enter the optic radiation of Gratiolet. This forms a large sagittal bundle which passes backwards and upwards, outside the posterior horn of the lateral ventricle, to the occipital lobe. The fibres from the lateral geniculate body tend towards the neighbourhood of the calcarine fissure. They are well seen in Weigert sections of the brain of the newly born child, the other fibres being unstained, owing to their medullary sheaths not having yet developed (Flechsig). Flechsig thinks that the fibres from the geniculate body end exclusively in the calcarine fissure and represent the fibres from the macula. Other fibres from the optic tract pass into the pulvinar of the optic thalamus, which very much resembles the external geniculate body in histological appearance. The cells here, around which the fibres arborise, are also optic neurons of the third order. We have already referred to the relation of their axons—dorsal t those derived from the geniculate body. Their ultimat distribution is probably less localised, extending over a larg area of the occipital lobe. The last group of fibres from th optic tract pass to the superior colliculus or corpu quadrigeminum. Although this has a complicated structur in man it is a mere rudiment as compared with its cond tion in the lower animals. Without going into the details c its structure in man it may be said that it consists c alternate layers of white and grey matter, the actual surfac being covered by a thin layer of white fibres. The functio of these is unknown; they do not degenerate after remov of the eye. The principal optic fibres enter the middle whit zone, which is separated from the superficial white layer b the superficial grey layer or cappa cinerea (Tartuferi). The terminal arborisations are around the cells in the superfici and also in the deeper grey matter. It is noteworthy th the deeper fibres pass to the region in which the fibres fro the lateral fillet end. These ganglion cells of the superi colliculus are also optic neurons of the third order. A fe of their axons pass to join the optic radiation, though this is doubted by some. Most of them pass down and bend round the grey matter surrounding the aqueduct of Sylvius, decussate with those from the opposite side beneath the third nuclei and the posterior longitudinal bundle, finally entering the posterior longitudinal bundle as they pass downwards towards the medulla. In their course they give off collaterals which pass to the opposite superior colliculus to the third, fourth, and sixth and probably to other nuclei. It is certain, at any rate, that they enter into intimate relation with the nuclei which govern the eye muscles, a fact which accounts for the mechanism of the eye muscle reflexes.

The effects of experimental destruction of the corpora quadrigemina are important. Most of the earlier observers—Flourens, Longet, McKendrick, Bechterew, Ferrier, and others—found a constant relation between the anterior lobes and the visual sense. The loss of vision following destruction depended upon the amount of decussation at the chiasma. In animals with total decussation—any below the rabbit, including the guinea-pig, birds, and fish—removal of one optic lobe caused blindness of the opposite eye. In animals with binocular vision heteronymous hemianopsia occurred, as Bechterew showed upon dogs; bilateral destruction produced complete blindness. More recent experiments on Testudo palustris (Fano) and birds (Stephani) show that the blindness is not complete. Nothnagel and Eisenlohr, from pathological data in man, found no interference with vision which could be ascribed to the corpora quadrigemina, and the later experiments of Ferrier and Turner contradict the earlier observation of Ferrier that complete blindness follows destruction of both superior colliculi in the monkey.

Confining our attention to primates, histological evidence all points to the dorsal and superficial layers as being most intimately connected with the visual afferent system, whilst the deeper layers are concerned with the ocular motor nuclei. Stimulation of the superior colliculus in monkeys causes, amongst other phenomena, widening of the palpebral fissures, elevation of the eyebrows, and conjugate deviation of the eyes to the opposite side, accompanied by a similar movement of the head and neck. These results may be attributed to spread of the current to the subjacent motor nuclei, but this is contra-indicated by the different effects obtained from the superior as compared with the inferior colliculi. Ablation causes temporary deviation of the eyes to the same side, lasting only a few hours. No ptosis or ophthalmoplegia follows as long as the lesion is not sufficiently deep to interfere with the third nuclei. The anatomical relations involve the removal of one occipital lobe, with consequent hemianopsia. Apart from this there are no visual effects which can be ascribed to the corpora quadrigemina.

We are forced to conclude that the superior colliculi are relatively unimportant as regards visual functions in primates, though they still probably retain some importance in the coördination of the ocular movements, acting principally as a reflex centre, receiving afferent impulses from the retinæ, the cortex, the acoustic-vestibular system, and the spinal sensory system through the fillet and cerebellum. These functions are too complex and too easily replaced vicariously to be elucidated by the coarse methods of experiment. As the size and importance of the mesencephalic visual nuclei diminish in ascending the animal scale, so the size and importance of the diencephalic nuclei—the lateral geniculate body and the pulvinar of the optic thalamus, both of which must be regarded as nuclei of the diencephalon—increase. The pulvinar is large only in primates. Excitation of the thalamus produces very little result: ablation results in visual defects. A very important pathological observation was made by Hughlings Jackson in 1875. There was localised softening of the posterior part of the right optic thalamus; the visual defect consisted in left hemianopsia. Ferrier and Turner and Lo Monaco from experimental lesions found contra-lateral hemianopsia plus amblyopia of the whole field.

We are now in a position to realise the parallelism which exists between the nuclei under consideration and those belonging to the afferent tracts of common sensibility. The ganglion cell layer is found to correspond with the nuclei gracilis and cuneatus, whilst the termination of the optic tract in the superior colliculus and thalamus (lateral geniculate body and pulvinar) corresponds with the terminations of the nucleo-thalamic (mesial fillet) tract in the mesencephalon and diencephalon respectively.

Ramon y Cajal divides the optic path from these lower centres to the occipital cortex in two parts—a superficial and a deep. The superficial path, which is the less important, arises in the superficial layers of the lateral geniculate body and possibly from the stratum zonale of the thalamus. It curves towards the middle line, passing into the "central optic path" (Ramon y Cajal) of the cerebral peduncle. The deep path arises from the deep cells of the lateral geniculate body as well as from the stratum zonale and enters the central optic path on its mesial border. Some of the axons entering the central optic path undergo bifurcation, one branch ascending with the main bundle into the corpus striatum, the other descending towards the tegmentum. Ramon y Cajal suggests that the descending branches may represent a reflex path between the visual centres and the motor nuclei for the eyes, head, and neck. Ramon y Cajal succeeded in following the axons of the central optic path throughout their entire course from their entrance into the corpus striatum to their termination in the occipital lobe in the newly born mouse. He found that they were distributed to those areas of the cortex in which the white stripe of Gennari is best developed. This agrees with the embryological results obtained by Flechsig.

The cerebral visual centres.—Since the early part of last century it has been known that the cortex cerebri in the neighbourhood of the calcarine fissure possesses a characteristic structure owing to the existence in the centre of the grey matter of a white line which is easily visible to the naked eye. This has been variously termed the line of Gennari, of Vicq d'Azyr, or of Baillarger, after the original investigators. Since the earlier descriptions of Meynert, Krause, and Betz this region of the cortex has received special attention from Leonova, Hammarberg, Schlapp, Cajal, and most recently and most exhaustively from Bolton. According to the last-named author the calcarine or visuo-sensory cortex may be divided into the following layers: (1) outer layer of nerve fibres; (2) layer of small pyramidal cells; (3*a*) outer layer of granules containing pyramids; (3*b*) middle layer of nerve fibres or line of Gennari, containing the solitary cells of Meynert; (3*c*) inner layer of granules; (4) inner layer of nerve fibres containing the solitary cells of Meynert; and (5) layer of polymorphic cells. In the neighbouring visuo-psychic cortex the layers are: (1) outer layer of nerve fibres; (2) layer of small and large pyramids; (3) layer of granules containing pyramids; (4) inner layer of nerve fibres; and (5) layer of polymorphic cells. The third layer is therefore split up in the calcarine region by the intercalation of white fibres which undoubtedly represent the terminations of the tecto-pallial fibres.

I put before you illustrations showing the distribution of the visuo-sensory area in a previously healthy man, aged 55 years, who died from right lobar pneumonia. The results were worked out by Bolton with enormous labour and care by means of serial sections and micrometer measurements. The area occupies the whole of the body of the calcarine fissure extending above to the parallel cuneal sulcus and below to the collateral fissure. It occupies the posterior part of the calcarine fissure, extending round the pole to the outer surface of the hemisphere to a considerable extent, being surrounded at its postero-external extremity by well-defined sulci. Anteriorly it extends along the lower lip of the stem of the calcarine fissure almost to its anterior extremity. Bolton examined five other occipital lobes from various cases, one of which was a case of anophthalmia. He concludes from this research that the specific area is approximately pear-shaped wit

thick end at the pole of the

tribution it occupies: (1) the

including the anterior and posterior annectants, and extending upwards to the parallel cuneal sulcus and downwards to the collateral fissure; (2) the posterior part of the calcarine fissure extending to the polar sulci surrounding its extremities; and (3) the inferior lip of the stem of the calcarine fissure (including the superficial surface and lower lip of the cuneal annectant) nearly to its anterior extremity, just posterior to which the area tails off to a sharp point. The area is much decreased in extent, but not in distribution, in cases of old-standing optic atrophy. In anophthalmia it is much contracted as regards both extent and distribution. It then occupies the usual position in the stem of the calcarine fissure but only extends backwards as far as the posterior cuneo-lingual annectant and it is confined to a portion of the inferior lip of the fissure and to the cortex between this and the collateral sulcus.

At the junction of the area of special lamination with the surrounding cortex the line of Gennari suddenly ceases. In the area itself the line is decreased nearly 50 per cent. in thickness in old-standing optic atrophy and the outer granule layer more than 10 per cent. On the other hand, in the cortex surrounding the area referred to old-standing optic atrophy causes no modification of the lamination. In anophthalmia the combined outer granule layer and line of Gennari are narrowed down to two-thirds of the normal thickness, the other layers of the cortex being approximately unchanged. This amount of narrowing is the same as that found in cases of old-standing optic atrophy. Hence it may be reasonably concluded that the area thus localised is the primary visual region of the cortex cerebri and that the part of this area to which afferent visual impulses primarily pass is the region of the line of Gennari. Bolton thinks that the area can probably be described as the cortical projection of the corresponding halves of both retinæ. In this projection the part above the calcarine fissure represents the upper corresponding quadrants and the part below the lower corresponding quadrants of both retinæ.

Ferrier first described the occipital lobes in various animals as being excitable and giving rise to movements of the eyes to the opposite side. In experiments with Yeo he found that destruction of the angular gyri in monkeys produced loss of vision of the opposite eye. This result has since been quite disproved by Schäfer and Sanger Brown and others, the explanation of Ferrier's results being probably the injury of the underlying fibres in the corona radiata passing from the occipital lobes. H. Munk first showed that removal of the occipital lobe alone in

dogs and monkeys by partial extirpations. He came to the conclusion that in the dog the upper part of the retina corresponds with the anterior part of the visual area, the lower with the posterior, the mesial or internal with the mesial or internal, and the lateral with the lateral. Central vision was most represented at the posterior pole. Schäfer and Sanger Brown came to the conclusion that in the monkey central vision is represented in the neighbourhood of the anterior part of the calcarine fissure. Schäfer considers that in the monkey and in man the whole of the visual area of one hemisphere is connected with the corresponding halves of both retinæ, that the upper zone of the visual area of one hemisphere is connected with the upper zone of the corresponding lateral halves of both retinæ, similarly for the lower zones, and that the focal point of the visual area, which is placed on the anterior part of the mesial surface of the occipital lobe, is connected with rather more than the corresponding halves of both maculæ. Pathological observations confirm these statements for the most part. Lesions of the occipital lobe produce hemianopsia without affecting the pupil reflexes. The fovea almost invariably escapes. Lesions of the mesial surface near the calcarine fissure produce the most serious disturbance for their size. Von Monakow limits the visual area to the cuneus, the lingual lobule, and the occipital gyri; all parts of the macula are represented in both hemispheres and over the whole visual cortex. According to Henschen the visual centre is confined to the neighbourhood of the calcarine fissure, the upper lip being connected with the upper quadrant of the retina, the lower with the lower quadrant, and the macula with the anterior part of the area, each macula being represented on both sides.

As far as anatomical evidence goes it seems certain that most of the fibres from the lateral geniculate body end in the region of the calcarine fissure. According to Henschen all the visual fibres of the optic tract end in the external geniculate body, whence new fibres are carried to the calcarine fissure. Flechsig, too, finds the termination of the fibres of Gratiolet's radiation in the mesial surface of the occipital lobe and a small area close to the longitudinal fissure. On the other hand, von Monakow and others trace the thalamo-occipital fibres to the whole of the occipital cortex and possibly to the posterior part of the parietal lobe; those from the external geniculate body pass principally to the cuneus and lingual lobule. The idea that the macular region is represented only in the anterior part of the calcarine fissure is opposed by some pathological observations, so that Förster and Sachs consider the posterior part of the fissure the more probable. This view is similarly negatived by other cases, so that it seems probable that the whole length of the calcarine fissure is concerned in representation of the macula (Barker). Von Monakow assumes a wide distribution of the macular fibres in the external geniculate body, so that almost any portion of the occipital cortex is capable of receiving macular impulses. This view is opposed by cases of localised bilateral lesions of the occipital lobes, causing complete blindness, though in some of these there has been double hemianopsia with partial escape of central vision.

The Hunterian Lectures

ON

FRACTURES OF THE SKULL.

Delivered before the Royal College of Surgeons of England on Feb. 29th and March 2nd and 4th, 1904,

BY LOUIS BATHE RAWLING, M.B. CANTAB., F.R.C.S. ENG.,

SENIOR DEMONSTRATOR OF ANATOMY, ST. BARTHOLOMEW'S HOSPITAL.

LECTURE II.[1]

Delivered on March 2nd.

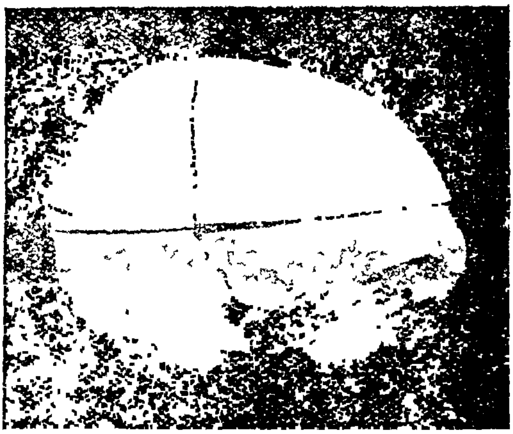
HÆMORRHAGES.

MR. PRESIDENT AND GENTLEMEN,—The various hæmorrhages that may result in skull fractures may be first classified into two main groups: (1) external hæmorrhages and (2) internal hæmorrhages. The first of the two groups may be subdivided into those hæmorrhages which result from basic fractures and those which are secondary to a fracture of the vault. The various extravasations into the tissues of the scalp would be included in the second subdivison, but as such hæmorrhages present but few points of new interest I do not propose, therefore, to discuss them further.

1. *External Hæmorrhages in Basic Fractures.*

Hæmorrhage from the ear.—The great majority of fractures which involve the middle fossa of the skull originate laterally at the external auditory meatus and pass inwards from that region towards the sphenoidal sinus. Both the roof and floor of the external auditory meatus may be involved, but the fracture is generally most marked along the roof. From this region the fracture passes towards the anterior and internal angle of the middle ear, the membrane undergoing a variable degree of destruction in the path of the fracture. The degree of membrane laceration corresponds to the severity of the fracture and the exact nature of the forces producing the fracture. For instance, if the fracture extends from the vault downwards to the base (Figs. 9 and 10) the membrane is generally torn in its upper and anterior part only, whilst if the fracture results from a direct blow on the auricular region the osseous injury is more extensive and the degree of laceration is added to by the forcible in-driving of air, whilst in the most severe cases the drum destruction is complete. The malleus and the incus undergo varying dislocations, but the stapes rarely undergoes any change in position. The blood which escapes from the ear will be seen to be derived from the lacerated cuticle lining the roof of the external meatus and also from a deeper region. Hæmorrhage is sometimes so profuse that one is quite unable to determine the exact source, but in favourable cases an otoscopic examination will reveal that the blood comes from the anterior and upper region of the tympanum, not so much from the torn drum itself but welling up fast through the gap in the drum. Post-mortem examination in such cases shows that the middle ear is full of blood derived from those torn tympanic vessels which, supplying the mucous lining and bony walls of the middle ear, lie in the path of the fracture.

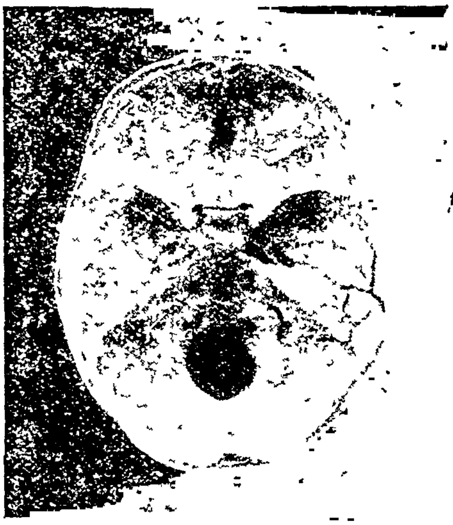
FIG. 9.



A fracture extending downwards from the vault to the base and involving the ear. The vault has been sawn through horizontally.

The amount of blood lost varies greatly. The escape may be profuse and may be continued for hours and even days, whilst in other cases there may be merely sufficient extravasation to clot and to dry up in the external meatus. I have had the opportunity of seeing several cases that throw light on the main causes which influence the amount of blood lost. The first case which drew my attention to the subject was as follows. A man was admitted with a wound on the right side of the head, the result of a fall, and with profuse hæmorrhage from the right ear, which lasted till death ensued, 14 hours later. The patient presented no symptoms pointing to extradural hæmorrhage, yet at the

FIG. 10.



Internal view of skull shown in Fig. 9. An extensive fracture of the middle fossa is present.

---

[1] Lecture I. was published in THE LANCET of April 9th, p. 973.

post-mortem examination a very extensive hæmorrhage from ound, whilst the tegmen the blood having a free ear and so externally through the lacerated membrana tympani. On going into the question, in subsequent cases, I observed (1) that hæmorrhage from the middle meningeal artery is very much more common than is generally supposed to be the case, the slighter forms yielding no clinical symptoms; and (2) that the fissures running across the tegmen tympani are usually of such a nature that blood can be forced through them into the middle ear.

It should also be pointed out that the extradural extravasation exercises a great mechanical pressure, and that as the extravasation increases so in direct ratio does the pressure exercised by it on the surrounding structures also increase. Relief, therefore, takes place in such cases by the passage of blood into the middle ear and through the torn membrana tympani. I regard, therefore, profuse and continuous hæmorrhage from the ear as very suggestive of an accompanying extradural hæmorrhage and although it is, perhaps, too much to advocate trephination over the artery in all such cases yet I am strongly of the opinion that such a method is advisable when the general conditions are grave, even in the complete absence of the typical symptoms of middle *meningeal hæmorrhage. It is hardly necessary to add that* the closure of the external meatus with a plug of gauze kept in position with wool and bandage is the worst possible treatment, and I have seen, at any rate, two cases where such methods quickly resulted in an increase of compression symptoms and in accelerated death. Both these cases presented on later examination all the features I have alluded to. The application of a plug in the meatus may, perhaps, be used for diagnostic purposes, the patient being carefully watched and any alteration in the symptoms pointing to pressure over the motor area promptly treated by trephination.

It will be of interest to narrate briefly a somewhat similar *case reported by Chassaignac.*[2] *A man after falling down* an area had continuous hæmorrhage from the ear lasting for three days. He kept to his bed but on the third day, feeling otherwise well, he got up and walked briskly to consult a "wise woman." On returning he complained of fatigue and headache, the hæmorrhage now having ceased. He became delirious and died. The examination showed an extensive *fracture of the petrous bone with laceration of the lateral* sinus and a great extravasation from a ruptured middle meningeal artery. The blood poured out had escaped freely for three days, the passage had then become blocked, and death resulted. In stating, therefore, that free hæmorrhage from the ear suggests strongly an extradural hæmorrhage from the middle meningeal artery it should be added that the blood may be derived from a lacerated venous sinus, this latter condition being, however, much more rare than the former.

Hæmorrhage from the ear does not, of course, necessarily imply the existence of a basic fracture. The membrane alone may be ruptured as the result of a blow on the ear. The resultant hæmorrhage is, however, seldom profuse and the absence of any further symptoms will soon clear up the diagnosis. From my own experience, however, I think that too much stress is laid on the fact that hæmorrhage from the ear results from other causes than a basic fracture and I regard this symptom, when secondary to a blow on the head, as practically diagnostic of the particular fracture of the *middle fossa to which I have alluded. In some few cases* hæmorrhage occurs from both ears, usually as the result of a bilateral compression, the fracture running from one external auditory meatus to the other, involving both tympanic cavities and the body of the sphenoid in the middle line. In these cases also the fracture frequently extends on either side up on to the vault in such a manner that the skull is practically *divided into two parts, merely* united by the soft structures. The prognosis in these cases is necessarily grave but the marvellous vitality of young adults enables them to recover even in such adverse circumstances.

Hæmorrhage into the nasal *cavity and into the naso-* or both of these cavities is ms in fractures of the base, for it occurs in nearly all fractures involving either anterior or middle fossæ. The post-mortem lesions found in these cases are comminuted fractures of the cribriform plate of the ethmoid and of the sphenoidal body.

I have already pointed out that most anterior fossa fractures traverse the cribriform plate of the ethmoid, a fairly free hæmorrhage resulting from lacerated ethmoidal arteries, whilst the very great majority of fractures of the middle fossa tend to pass through the sphenoidal body. Now this sphenoidal body, which is in reality one of the weakest of the basic areas, consists of a mere shell of body inclosing the air sinus and bounded laterally by the cavernous sinus, on the outer side of which the internal carotid artery runs. The liability of this region to injury is so marked that although a fracture passing along the anterior border of the petrous bone may tail off before reaching this region, yet in many cases the conducted forces suffice to bring about an extensive fracture on reaching the sphenoidal body. These fractures are generally comminuted, both roof and floor of the sinus being equally damaged in such a manner that a probe may be passed from the cranial cavity into the naso-pharynx below. The comminuted sinus wall punctures or tears the cavernous sinus, profuse hæmorrhage resulting, whilst in the most severe cases the internal carotid artery itself may be completely torn across. In the only two cases that I have seen where the carotid artery was torn blood poured into the naso-*pharynx, gushed from the mouth in streams, and death*

The results produced both from actual nd from pressure on the nerves supplying the muscles; (2) subconjunctival hæmorrhage; (3) palpebral and peri-palpebral hæmorrhage; and (4) proptosis. The muscular paralyses will be alluded to under "nerve implication"; the other symptoms need, however, further reference.

Subconjunctival hæmorrhage.—Hæmorrhage beneath the conjunctiva nearly always makes its appearance at the outer canthus of the eye, progressing inwards towards the corneoscleral margin. *In the more marked cases the extravasation* may completely surround the cornea, bulging forwards so as almost completely to obliterate the field of vision. Even in these cases, however, the hæmorrhage is most extensive at the outer canthus. When combined with some degree of proptosis, the probable fracture present is one which involves the region of the sphenoidal fissure, with implication of the *anterior part of the cavernous sinus. When no proptosis is* present the fracture is commonly due to a blow in the temporal region involving the outer orbital wall.

Palpebral and peri palpebral hæmorrhage.—Hæmorrhage into the eyelids and into the loose connective tissue surrounding the lids is seen in most cases of anterior fossa fractures. It frequently coexists with subconjunctival hæmorrhage but the two are not necessarily present together. It differs from subconjunctival hæmorrhage in its site of early origin, for palpebral hæmorrhage nearly always begins at the inner angle of the eye, progressing outwards into the tissues of the upper and lower lids and into the surrounding regions. The extravasated blood may be wholly anterior to the tarsal and ligamentous structures of the lids, in which case the fracture usually involves the perpendicular plate of the frontal bone only. More commonly, the fracture extends along the orbital roof, perhaps involving the sphenoidal sinus, in which case palpebral hæmorrhage, subconjunctival hæmorrhage, and proptosis may all three be present together.

Proptosis.—The time at which proptosis first becomes evident and the degree to which it progresses are both very variable. One can, however, tabulate these cases roughly into three main groups and from them draw certain conclusions as to the probable nature of the injury present.

1. Proptosis severe, appearing almost at once, and progressive.	1. A severe fracture in the region of the sphenoidal fissure and cavernous sinus with
2. Proptosis moderate and appearing after a few hours.	2. A fracture involving the orbital walls, the extravasated blood being derived from lacerated ophthalmic vessels.
3. Proptosis appearing days or weeks after the injury and usually steadily progressive.	3. A fracture involving the region of the cavernous sinus with injury to the internal carotid artery and with the formation of a fistulous communication between the sinus and the artery.

---

[2] Plaies de la Tête, 1842.

I have alluded several times to the sphenoidal fissure as a region which, when involved, may result in fairly extensive hæmorrhage. I should remind you, perhaps, that the orbital branch of the middle meningeal artery runs forwards to the orbit at the outer angle of the fissure and that this vessel is commonly injured in all fractures involving this region, adding, therefore, to the blood extravasation which results from fractures involving this region.

Hæmorrhage into the mastoid and occipital regions.—In fractures of the posterior fossa the blood poured out has but little chance of making itself evident owing to the dense mass of muscles and fasciæ which overlie that fossa. The resistance offered by these structures tends to confine the extravasated blood to the cerebellar fossæ, adding consequently to the already grave prognosis of fractures in this region. Sometimes careful palpation will detect a "doughy" or "boggy" condition of the tissues and ecchymosis may appear later from the extravasation of blood upwards on to the vault and downwards into the neck. A peculiar ecchymotic patch is frequently seen, appearing first in front of the apex of the mastoid process and travelling upwards in a curved direction, concavity forwards, following the outline of the external ear. This ecchymosis is said to result from the tracking of blood upwards along the course of the posterior auricular artery. In all the cases that I have seen this condition was associated with a separation along the occipito-mastoid suture and although this suture and the line of the hæmorrhage do not quite coincide there must, I think, be some connexion between the two. Before passing on to the subject of intracranial hæmorrhages I wish to return to the subject of

"Orbital aneurysm."—The first complete account of this complication was given by Rivington in 1875.[3] I have collected 20 further cases, in all of which the history and other symptoms strongly indicated the previous existence of a basic fracture. 16 of these cases were males and four were females. The average age of the males was 22 years and that of the females was 33½ years. The injury consisted of blows or falls on the head in 18 cases and of punctured wounds of the orbit in two cases.

I will pass over most of the more important subjective and objective symptoms, confining myself mainly to the question of treatment. In discussing this, however, it is necessary to pick out one or two of the more important symptoms so as to obtain some record as to the way they are affected in the various methods adopted. Proptosis is usually the first symptom to appear and many patients come for advice complaining of nothing more than some prominence of the eyeball, combined usually "with noises in the head," compared to the whirring of machinery, the buzzing of bees, or the thud of a steam-hammer. This proptosis generally appears during the second month, though occasionally its onset is much earlier, and in one case was not noticed till nearly a year after the accident. The eyeball is dislocated downwards and outwards, the main pulsating tumour occupying the upper and inner angle of the orbit. All the main symptoms were diminished by compression of the common carotid of the affected side and the symptoms steadily increased in most cases when no treatment was adopted, the globe being pushed further and further out of its socket, even on to the cheek. The cornea sloughed and the eye was completely destroyed. Repeated and profuse hæmorrhage will ultimately lead in these cases to a fatal result. In some few cases the symptoms remained quiescent, whilst in others expectant treatment resulted in marked improvement. The treatment adopted in these 20 cases was as follows. 1. In 12 cases the common carotid was tied with a primary ligature in six cases and with a secondary ligature after failure of other methods in six cases. The result was great improvement in all. 2 In four cases no treatment was adopted beyond rest, &c., combined with the administration of sedatives and of iodide of potassium in large doses, with the result that two improved in their general condition, one remained *in statu quo*, and the fourth case was unable to be traced. 3 In ten cases digital or instrumental pressure on the common carotid was tried first, with the result that three showed marked improvement, one remained *in statu quo*, whilst in the other cases, either on account of the pain produced or from failure to obtain any satisfactory result, the common carotid was ligatured, in each case with an immediate successful result. The actual method of compression adopted varied in the different cases; in some a continuous mechanical pressure was used by means of an instrument, whilst in others an intermittent digital method was tried. In one case continuous pressure was adopted for one month and in another intermittent pressure was used for ten weeks, and in each case the result was a complete failure to produce a successful result. In the 12 recorded cases where the common carotid was ligatured the result obtained was an immediate success, the main aneurysmal symptoms rapidly disappeared, the pulsation ceased, the proptosis diminished, and the patients were later able to return to their former occupation. In one case only, however, was there a complete return to the normal, for in all the others some permanent defect in vision remained, due mainly to the previous stretching of the parts, and in two cases the operation was not carried out sufficiently early to prevent some sloughing of the cornea. The noises in the ear, also, though much diminished, occasionally remained permanently.

The conclusions to be drawn from these cases, according to the method adopted, are as follows: 1. By means of rest, &c., the progress of the disease may be arrested and marked improvement may result. 2 Compression, digital or instrumental, intermittent or continuous, is painful, tedious, and uncertain as to its result. 3. Ligature of the common carotid will almost certainly greatly improve the local conditions and will probably effect a cure, and the earlier the ligation is performed the greater is the chance of reducing to a minimum the subsequent corneal sloughing, &c. No cerebral disturbances need be feared as a result of tying the common carotid unless as a result of the original injury some laceration of the same side of the brain be present. In such cases it is best to accustom the brain to its future condition by some "preparatory" form of treatment as could be brought about by occasional intermittent pressure before the more radical treatment.

Post-mortem evidence of the lesion present.—Three of Rivington's cases showed a direct communication between the internal carotid artery and the cavernous sinus. In the 20 subsequent cases which I have collected an examination was only held in one and in this case the artery communicated with the sinus by two rounded holes through which the arterial blood was pumped into the cavernous sinus. A united fracture of the petrous bone ran inwards towards the sinus.

The basic fracture peculiar to these cases.—I have previously pointed out that in basic fractures, wherever the injury may be received, the body of the sphenoid, forming one of the weakest of the basic areas, is especially liable to injury, and I shall show later two specimens where the internal carotid artery was lacerated in this region. The exact line of the fracture is not stated in the majority of the recorded cases, but putting all the facts together it appears probable that when orbital aneurysm results from a blow on the head the most common fracture producing such a result will be one which travels along the anterior border of the petrous bone to the cavernous sinus, injuring the internal carotid artery as it runs forwards along the outer part of the cavernous sinus.

2. *Internal Hæmorrhages.*

According to the relation of the extravasated blood to the meninges and cerebrum these hæmorrhages may be classified in the following groups: (1) extradural; (2) intradural; (3) cortical; and (4) intraventricular.

Extradural hæmorrhage may be arterial or venous, in the former case the blood being derived almost exclusively from the middle meningeal artery. A purely venous extradural hæmorrhage is occasionally seen in connexion with fractures of the posterior fossa, in those rare cases where the lateral sinus is mainly torn on its outer aspect. The extravasated blood is unable to find any means of escape owing to the dense mass of muscles attached to the occipital bone, and as the dura mater is in this region but loosely applied an extensive extradural clot results. The middle meningeal artery and its numerous branches are necessarily very liable to injury in all fractures involving the temporal region and the middle fossa of the skull, the anterior branch of the artery being especially liable to such injury. The anterior branch may be torn in the temporal region and so secured with comparative ease, whilst in other cases the main artery, or one of its branches, may be cut across low down in the basic fossa by a fracture travelling obliquely across the middle fossa. In these cases no ordinary trephination will suffice to reach the bleeding point. In the great majority of cases the vessel is lacerated on the same side as that on which the injury was received, but occasionally the hæmorrhage occurs on the opposite side and is not necessarily associated with a corresponding basic fracture. Such cases are almost confined to late life, when the arteries are atheromatous. English records three cases, all of which were fatal, where both vessels were injured.

---

[3] Transactions of the Royal Medical and Chirurgical Society, vol. lviii.

Uncomplicated middle meningeal hæmorrhage is rare and the coexistence of a fracture of base or vault, with the addition of brain laceration, renders a correct and early diagnosis exceedingly difficult and often impossible. I have previously pointed out that the pressure effects depend to a large extent on the presence or absence of a safety valve such as is afforded by the existence of a comminuted fracture of the tegmen tympani, allowing of the escape of blood into the middle ear and so externally through the gaps of a lacerated drum. A safety valve is also provided in those cases where the meningeal hæmorrhage is associated with a comminuted fracture of the temporal fossa walls, in which case the extravasated blood escapes into the temporal muscle, leading to swelling, ecchymosis, and even pulsation in that region. Compression of this temporal hæmatoma results in an increase of the general compression symptoms and also occasionally leads to twitchings, &c., of the muscles of the opposite side of the face and body. The amount of blood extravasated varied in the different cases from one drachm to several ounces, the largest coagulum being four and a half [illegible] The clot, partly fluic[illegible], except on the dura [illegible] the clot leaving the dura mater rough, fibrinous, and discoloured. The dura mater is firmly adherent along the upper border of the temporal bone and also along the lesser wing of the sphenoid, whilst the intervening portion is but loosely attached to the underlying bone of the middle fossa. The blood first poured out has a comparatively easy task in lifting up this loosely applied dura mater, but though exercising an ever greater mechanical pressure as the size of the clot increases, yet it has now to meet insurmountable difficulties in front, behind, and on the inner side, with the result that the blood forces its way upwards towards the convexity of the brain.

Krönlein divides middle meningeal clots into three main varieties, according to the area of brain mainly compressed: (1) temporo-parietal (the commonest); (2) parieto-occipital (rare); and (3) parieto-frontal (very rare). The great difficulties which arise in the diagnosis of an extradural hæmorrhage are evidenced by the following group of cases. An extradural hæmorrhage, of a greater or lesser degree, was found in 30 per cent. of all cases where a post-mortem examination was held and a previous diagnosis was made in 9 per cent. of cases only. The question at once arises as to what are the most important and most suggestive features indicating the probable presence of such a hæmorrhage for the typical symptoms are generally obscured by the presence of other lesions. From my own experience I should put the suggestive symptoms in the following order, according to the frequency of occurrence: (1) the presence of a temporal hæmatoma; (2) a copious and continued hæmorrhage from the ear; (3) twitchings of the facial muscle of the opposite side and twitchings or spasticity of the muscles of the opposite arm and leg; (4) a brief lucid interval between the stages of concussion and collapse; and (5) some alteration in the pupil of the affected side, more commonly a "constricted" pupil. The dilated or Hutchinson pupil is, according to my experience, but rarely seen, except in the later stages, when its diagnostic value is of less importance as the "crisis" is passed. Hutchinson concluded that the dilated pupil was the result of direct pressure on the third nerve. Against this view two points may be urged: (1) no other symptoms pointing to pressure on the nerve are present nor are any of the accompanying nerves involved; and (2) the hæmorrhage would need to overcome almost insurmountable difficulties in order to lift up the dura mater as far as the outer wall of the cavernous sinus. Pagenstecher and H. P. Dean have also shown that localised compression on the cortical motor areas affects the pupil of the same side, producing fir[illegible] the pupil. The pupil [illegible] in origin. The temp[illegible]lse are so variable that no dependence can be placed on them.

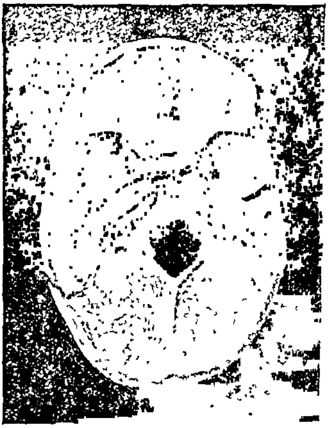
In trephining it is necessary to operate at the earliest possible moment and in doubtful cases it is better to operate and to find no hæmorrhage than to defer any radical treatment till too late. It is frequently necessary to chip away the bone towards the base, as the artery is often torn, low down in the base, soon after the bifurcation. If all local measures fail to reach the bleeding spot it will be necessary to tie the common or external carotid artery. Liddell, in the *American Journal of the Medical Sciences*, reported two cases where it became necessary to ligature the common carotid artery, the result being in each case successful. It is, however, probably advisable to tie the external carotid in preference to the common carotid artery, the brain being already compressed and probably lacerated and any further interference with its blood-supply may lead to serious early and remote cerebral changes.

Prognosis.—This is best illustrated by the 257 cases collected by Weismann. In 110 cases operated on the mortality was 27 per cent. In 147 cases not operated on the mortality was 88 per cent. In estimating the value of early surgical treatment in connexion with these statistics it must be borne in mind that the majority of the fatal cases not operated on were probably inevitably fatal, owing to the presence of other lesions of the skull and the brain. Weismann's cases would have been of greater value if they were grouped after Jacobsen's plan: (1) hopeful cases; (2) less hopeful cases; and (3) cases hopeless from the first.

Injury to the internal carotid artery.—This vessel, during its passage forwards and inwards towards the posterior clinoid process, lies behind the ordinary fracture which passes across the middle fossa, but as it passes forwards in the outer wall of the cavernous sinus towards the anterior clinoid process it crosses the line of fracture from one middle fossa to the other. Although it is loosely imbedded in the sinus wall, protected by nerves on its outer side, and situated well above the basic level, yet it is in this part of its course that it is liable to injury. I shall show you two such cases, one in which both vessels were completely torn across, a fracture passing from one middle fossa to the other with such marked separation of the anterior and posterior segments of the skull that the two parts were freely moveable, one against the other (Fig. 11), whilst in the second case a fracture, originating in the left frontal region, passed [illegible] sphenoidal region [illegible] the body of the [illegible]us and partially [illegible] artery (*Fig. 12*). Death in each case was nearly instantaneous, blood gushing from the mouth and the nose. The injury to the artery may be in other cases so slight that a fistulous communication between the artery and sinus results, with the formation of an orbital aneurysm.

Hæmorrhage from venous sinuses.—Two of the cerebral venous sinuses are placed in such a situation that they incur

FIG. 11.



An extensive fracture passing through the sphenoid from one middle fossa to the other.

I have alluded several times to the sphenoidal fissure as a region which, when involved, may result in fairly extensive hæmorrhage. I should remind you, perhaps, that the orbital branch of the middle meningeal artery runs forwards to the orbit at the outer angle of the fissure and that this vessel is commonly injured in all fractures involving this region, adding, therefore, to the blood extravasation which results from fractures involving this region.

Hæmorrhage into the mastoid and occipital regions.—In fractures of the posterior fossa the blood poured out has but little chance of making itself evident owing to the dense mass of muscles and fasciæ which overlie that fossa. The resistance offered by these structures tends to confine the *extravasated* blood to the cerebellar *fossæ*, *adding* consequently to the already grave prognosis of fractures in this region. Sometimes careful palpation will detect a "doughy" or "boggy" condition of the tissues and ecchymosis may appear later from the extravasation of blood upwards on to the vault and downwards into the neck. A peculiar ecchymotic patch is frequently seen, appearing first in front of the apex of the mastoid process and travelling upwards in a curved direction, concavity forwards, following the outline of the external ear. This ecchymosis is said to result from the tracking of blood upwards along the course of the posterior auricular artery. In all the cases that I have seen this condition was associated with a separation along the occipito-mastoid suture and although this suture and the line of the hæmorrhage do *not quite* coincide there must, I think, be some connexion between the two. Before passing on to the subject of intracranial hæmorrhages I wish to return to the subject of

"*Orbital aneurysm.*"—The first complete account of this complication was given by Rivington in 1875.[3] I have collected 20 further cases, in all of which the history and other symptoms strongly indicated the previous existence of a basic fracture. 16 of these cases were males and four were *females*. The average age of the males was 22 years and that of the females was 33½ years. The injury consisted of blows or falls on the head in 18 cases and of punctured wounds of the orbit in two cases.

I will pass over most of the more important subjective and objective symptoms, confining myself mainly to the question of treatment. In discussing this, however, it is necessary to pick out one or two of the more important symptoms so as to obtain some record as to the way they are affected in the various methods adopted. Proptosis is usually the first symptom to appear and many patients come for advice complaining of nothing more than *some prominence of the* eyeball, combined usually "with noises in the head," compared to the whirring of machinery, the buzzing of bees, or the thud of a steam-hammer. This proptosis generally appears during the second month, though occasionally its onset is much earlier, and in one case was not noticed till nearly a year after the accident. The eyeball is dislocated downwards and

the sigmoid and the lateral sinus. This part corresponds to the occipito-mastoid suture and separation along the line of this suture is a frequent sequel to blows received in that region. The degree of separation is [illegible] great and this, combined with the dural tr suffices extensively to lacerate th

adopted varied in the different cases; in *some* a continuous mechanical pressure was used by means of an instrument, whilst in others an intermittent digital method was tried In one case continuous pressure was adopted for one month and in another intermittent pressure was used for ten weeks, and in each case the result was a complete failure to produce a successful result. In the 12 recorded cases where the common carotid was ligatured the result obtained was an immediate success, the main aneurysmal symptoms rapidly disappeared, the pulsation ceased, the proptosis diminished, and the patients were later able to return to their former occupation. In one case only, however, was there a complete return to the normal, for in all the others some permanent defect in vision *remained*, due *mainly to* the previous stretching of the parts, and in two cases the operation was not carried out sufficiently early to prevent some sloughing of the cornea. The noises in the ear, also, though much diminished, occasionally remained permanently.

The conclusions to be drawn from these cases, according to the method adopted, are as follows: 1. By means of rest, &c., the progress of the disease may be arrested and marked improvement may result. 2 Compression, digital or instrumental, intermittent or continuous, is painful, tedious, and uncertain as to its result. 3 Ligature of the common carotid will almost certainly greatly improve the local conditions and will probably effect a cure, and the earlier the ligation is performed the greater is the chance of reducing *to a minimum* the *subsequent* corneal sloughing, &c No cerebral disturbances need be feared as a result of tying the common carotid unless as a result of the original injury some laceration of the same side of the brain be present. In such cases it is best to accustom the brain to its future condition by some "preparatory" form of treatment as could be brought about by occasional intermittent pressure before the more radical treatment.

Post-mortem evidence of the lesion present.—Three of Rivington's cases showed a direct communication between the internal carotid artery and the cavernous sinus. In the 20 subsequent cases which I have collected an examination was only held in one and in this case the artery communicated with the sinus by two rounded holes through which the arterial blood was pumped into the cavernous sinus. A united fracture of the petrous bone ran inwards towards the sinus.

The basic fracture peculiar to these cases.—I have previously pointed out that in basic fractures, wherever the injury may be received, the body of the sphenoid, forming one of the weakest of the basic areas, is especially liable to injury, and I shall show later two specimens where the internal carotid artery was lacerated in this region. The exact line of the fracture is not stated in the majority of the recorded cases, but putting all the facts together it appears probable that when orbital aneurysm results from a blow on the head the most common fracture producing such a result will be one which travels along the anterior border of the

directly or indirectly along [illegible] may help in the diagnos chemical examination of the fluid may help in the diagnosis, since the two fluids differ appreciably in composition.

1. *Cerebro-spinal fluid* is rich in chlorides, contains little or no albumin, and a trace of a reducing substance allied to pyrocatechin.	2. *Fluid derived from other sources* contains chlorides, a fair amount of albumin, and no reducing substance.

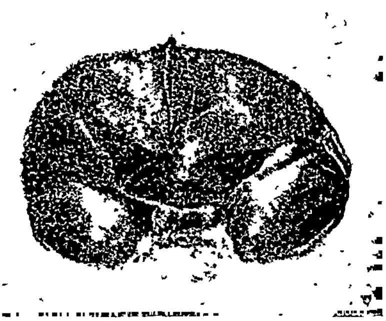
Certain factors, however, enter into the case which neutralise the advantages of a chemical analysis, for even though the fluid be *cerebro-spinal* in nature it is frequently mixed with blood, with the consequent addition of albumin, whilst if the fluid be profuse in amount the first part only contains any reducing substance, the fluid soon becoming a mere serous exudation. I have several times been able to collect a clear fluid from the ear, drop by drop, in a test-tube, and I have generally failed to demonstrate the presence of this reducing agent, though the post-mortem examination evidenced later that the fluid was derived from the subarachnoid space. The fluid is almost certainly cerebro-spinal in nature: (1) if the discharge begins within 24 hours of the accident; (2) if the discharge is colourless and profuse; and (3) if the discharge continues for some days. The time of onset, the duration, and the quantity are all, however, subject to great variation. 1. The time of onset is usually early, but cases are recorded where the discharge began weeks after the accident. 2. The duration may be from a few hours to many weeks. Sir W. Savory recorded a case where fluid escaped for one month from both ears. 3. The quantity varies from a few ounces to several pints. Sir

William MacCormac described a case in which three pints escaped in five hours.

This occasional great loss of fluid is due to the fact that as the cerebro-spinal fluid escapes the pressure in the subarachnoid space is practically reduced to zero, and since the cerebro-spinal tension and the intracranial venous pressure are equal fluid continually passes from the veins into the subarachnoid space as long as the cerebro spinal fluid escapes.

Cerebro-spinal fluid from the nose.—Blandin, of the Hôtel Dieu, first drew attention to this symptom in 1840. The gross lesion most commonly present is a comminuted fracture of the cribriform plate of the ethmoid, with laceration of the overlying dura mater and arachnoid (Fig. 14). More rarely the fluid may be derived from the cisterna basalis, the fracture involving the sphenoidal body with laceration of the overlying membranes and with comminution of both roof and floor of the sinus. Goucard and Malgaigne both describe cases where, as the result of a severe fracture of the petrous bone without injury to the membrana tympani, the fluid escaped forwards into the naso-pharynx along the Eustachian tube.

FIG. 14.



The crista galli with a fracture passing through the cribriform plate on the right side.

Cerebro-spinal fluid from the ear.—This was first recorded by van der Wiel in 1727, and more completely by M. Laugier in 1839. The source of the fluid is usually stated to be as follows: "The fracture involves the petrous bone in such a way that the arachnoid and dural sheaths round the seventh and eighth pairs of nerves are torn, allowing the cerebro-spinal fluid to escape into the middle ear, and so externally through a torn membrana tympani." The great majority of fractures which involve the petrous bone pass in front of the genu of the seventh nerve and in front of the eighth nerve and internal ear. Some further lesion is therefore necessary, and it will be found that two main varieties of fracture may lead to aural discharge of cerebro-spinal fluid. 1 A fracture of the middle fossa, with such comminution of the petrous bone that the subarachnoid space is opened up, either directly by laceration of the dura mater and arachnoid overlying the tegmen tympani or indirectly by involvement of the membranous prolongations along the seventh and eighth nerves. 2. A fracture of the posterior fossa which, on reaching the jugular foramen, cuts across the petrous bone, traversing the vestibule, and severing the facial nerve in the region of the genu. The external signs of injury and the condition of the facial muscles will generally suffice to make clear which variety of fracture is present.

Prognosis and treatment.—The discharge of cerebro-spinal fluid does not materially influence the prognosis. Large quantities of fluid may be lost without any striking effect, and though the existence of such a discharge necessarily indicates the opening-up of the subarachnoid space to the exterior, yet the danger of infection does not appear to be increased proportionately, the outflow tending, no doubt, to wash away any micro-organisms present in the external meatus. Battle records 36 cases with a mortality of 25 per cent., and another writer 11 cases with a mortality of 27 per cent., the general mortality in all cases of fractured base being estimated at 32 per cent. As regards the special treatment in these cases it is most inadvisable to syringe out the ear, as by such means a stream of fluid is driven into the middle ear and even further if the tegmen, for instance, be extensively comminuted, the danger of infection being proportionately increased. The meatus should be merely swabbed out with some strong antiseptic, a little iodoform powder lightly blown in, and absorbent protective dressings applied, the whole being maintained accurately in position by firm and efficient bandaging. Frequent changing of the dressings may be necessary when the discharge is profuse. The patient must be carefully watched in case attempts may be made to interfere with the bandages and such action prevented by tying down the hands to the side. It is important to bear this in mind as such attempts are frequently made. When the fluid escapes from the nose or into the naso-pharynx little can be done to lessen the risk of infection, and as a result meningitis is most commonly secondary to a fracture of the anterior fossa.

A CHRONIC NEUROSIS CHARACTERISED BY FREQUENT PAROXYSMS OF PAIN, SWELLING, AND HÆMORRHAGE IN VARIOUS PARTS OF THE BODY; DEATH FROM ACUTE PULMONARY TUBERCULOSIS.

BY T. K. MONRO, M A., M.D., F.F.P.S. GLASG.,
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY AND PROFESSOR OF MEDICINE IN ST. MUNGO'S COLLEGE;

AND

A. N. McGREGOR, M.D. GLASG.,
ASSISTANT SURGEON TO THE GLASGOW ROYAL INFIRMARY.

THE patient was a man, aged 28 years, who, about seven years ago, had an attack characterised by pain and swelling in both knees. The illness began at about 10 o'clock one morning while he was standing at his work and the pain grew steadily worse until it compelled him to cease working at 4 P.M. The skin over the inflamed joints pitted on pressure. Great relief was obtained on lying down, but as the pain subsided discolouration appeared. The pain extended down to the feet but the swelling was confined to the region of the knees. The swelling disappeared some 12 hours after the pain ceased. After two days in bed without special treatment the patient felt quite well again. After two months of good health the two elbows became the seat of pain, swelling, and discolouration such as had previously involved the knees. In the articular attacks swelling and pain began almost simultaneously, the discolouration only appearing after the attack had reached its height and was commencing to subside. Active or passive movement of the affected joints caused intense pain. In some attacks fluctuation was quite distinct in the joints; in others the lesion appeared to be periarticular. Similar attacks occurred in the fleshy parts of the limbs—e.g., the calves, the thighs, the forearms, and the upper arms. The lesions often affected the limbs of both sides but were not always strictly symmetrical. Sometimes the four limbs were involved simultaneously. Small, red, slightly elevated spots occasionally appeared on the legs with some itching but without pain. Moreover, local irritation, as in working with the hands or in treading on a pebble, would cause red elevated blotches to appear on the hands or feet. These blotches were surrounded by a white ring and were associated with great heat and itching. They would disappear in a day or two and leave no staining behind them. The severe attacks were sometimes associated with malaise, slight shivering, and considerable thirst, but there was no headache or vomiting. In connexion with the attacks a little blood might be passed by the bowel, but the patient never observed blood in the urine and no blood escaped from the nasal or buccal mucous membrane. About three and a half years ago a painful lesion developed in the scrotum and spread to the penis. At a later date a similar attack began in the penis and spread to the scrotum.

This condition was accompanied by great pain and discolouration. About three years ago the patient began to suffer in his chest. He thought he was always getting cold and for a long time he was never free from such symptoms. The sputum varied from time to time and might be chiefly mucous, or thick and yellow, or again might contain a large or a small amount of blood. After the chest began to suffer, the severe attacks tended to involve the soft parts of the limbs more and the joints less than formerly. The pulmonary attacks were associated with pain and cough and lasted longer than the articular attacks. The temperature in a pulmonary attack was observed to be as high as 103° F. In the last few years of the patient's life pulmonary lesions seemed to develop frequently and yet, apart from progressive shrinking of the left lung, the abnormal physical signs cleared up time after time in a remarkable manner. On one occasion, two and a half years ago, the patient was working on his knees on a carpet for one and a half hours. About an hour afterwards a red blotch as large as a florin appeared on that part of each knee on which his weight had rested and in the course of some hours more there was great swelling with pain which was described as frightful. A soft painless swelling extended down to the feet. The attack in the knees detained the patient for two days in bed and left the parts black and blue. The tongue had often been the seat of patches of discolouration but usually without pain. The first occasion, so far as is known, was about two and a half years ago. With the exception, on one occasion, of the left upper eyelid, the face was never affected. In October, 1902, the patient felt his throat sore one afternoon as if he had got cold. By 7 P.M. pain set in and this was followed after a time by a sense of suffocation. Before three o'clock on the next morning he was suffering from orthopnœa. A swelling was observed behind the left tonsil and in the posterior part of the pharynx. At 10 A.M., when the attack was subsiding, it was found that swelling was present in the region of the false vocal cords to such an extent as to prevent examination of the parts further down. There was still some puffiness in the pharynx and behind the left tonsil.

The interval between the paroxysms in this disease varied. A period of two weeks was common and the longest was about four weeks. Each attack consisted of a series of lesions, varying from three to seven in number and involving in succession the joints, the skin, the lungs, and other parts. The duration of an ordinary attack was about a fortnight. In the later years the feet sometimes perspired excessively. The palms of the hands were affected in the same way but in less degree. Necrosis of tissue was never observed.

In the course of a detailed examination carried out in October, 1902, the following data were obtained. The urine contained no albumin or sugar but tended to deposit uric acid on standing. The digestive system was in good order. The appetite was good and the bowels were regular. No abnormality was discovered in the liver, spleen, or superficial lymph glands. The apex beat of the heart was in the fifth intercostal space slightly external to the nipple line. The left border of cardiac dulness was one inch outside the nipple line. The right border was a little to the left of the left sternal margin. The upper border was at the third intercostal space. The sounds were normal. The sputum consisted chiefly of frothy mucus. Dr. D. McCrorie, bacteriologist to the Glasgow Royal Infirmary, found that neither the tubercle bacillus nor the pneumococcus was present. The patient was liable to night sweats in connexion with the pulmonary attacks as well as in the severe articular attacks. Percussion was impaired in the left front and consonating râles were heard in the same region but the vocal fremitus and the vocal resonance were not definitely altered. At the back there was very slight impairment of percussion at the left apex. Crackling sounds, suggestive of pleural friction, were heard at the middle of the left back. An occasional dry râle was heard on the right side of the chest. The size and the movements of the chest were diminished on the left side. Investigation of the functions of the cranial nerves revealed nothing of importance. The sense of smell was not so acute on the left side as on the right. The pupils were large. Hearing was fair in both ears. The tongue deviated slightly to the left when protruded but could be fully turned to the right at will. In other respects the examination yielded normal results. The fundi oculorum were healthy. The knee-jerks were exaggerated but there was no ankle clonus. The plantar reflexes were absent. The feet were somewhat cold, moist, and livid, with a sluggish circulation. The cremasteric, abdominal and epigastric reflexes were active. The nutrition of the muscles was good but the patient had lost weight. Paresis, incoördination, disturbance of any kind of sensation, delayed conduction, girdle sensation, bullæ, changes in the hair and nails, clubbing of the digits, disturbances of the bowels or bladder, and tenderness and deformity of the spine were all entirely absent. The mental faculties were likewise unimpaired.

Examination of the blood showed that the red corpuscles were normal in form and size and formed rouleaux as in health. They numbered 5,400,000 per cubic millimetre. The white corpuscles numbered 10,000 per cubic millimetre. The hæmoglobin was 75 per cent. of the normal. A bacteriological examination by Dr. McCrorie showed that the blood was sterile. On different occasions in the month of February, 1903, Dr. Hugh H. Borland determined the coagulability of the blood by means of Wright's coagulometer and obtained normal results.

In March, 1903, it was noted that during the past 11 months there had been no material change in the patient's general condition. He seemed to consider that he was not losing ground. There was now little or no expectoration and the night sweats had ceased. The signs of shrinking of the left lung, however, were rather more marked. There was distinct retraction of the left front of the chest. The left border of cardiac dulness was one and a half inches outside the nipple line and the right border was an inch to the left of the left sternal margin. Percussion was impaired over the front and side as well as the upper part of the back of the left chest. On the affected side the respiratory murmur was diminished, bronchial breathing could be heard above the clavicle, and scanty crackles, probably due to pleural friction, were detected over the back. Early in February, 1903, a large hæmorrhage occurred in the mouth, involving principally the soft palate but extending down to the pillars of the fauces on the left side. This was associated as previously with some œdema but neither the hæmorrhage nor the œdema was so great as in the previous attack in the throat. Shortly after this there was a large hæmorrhage in the left chest wall extending vertically from the angle of the scapula to the lower costal margin and extending horizontally (at its widest part) from the middle line behind to two inches in front of the mid-axillary line. These phenomena abated rapidly though minute lesions were continually appearing and disappearing. At the commencement of this attack he was admitted to the Glasgow Royal Infirmary for three weeks and during the last week of his residence and for two months thereafter he had applications of high-frequency currents for 20 minutes daily. At this period the muscular pains were sometimes very severe in the legs but the arms were seldom affected. To give a fair idea of the daily variations of the symptoms the following notes are extracted from the patient's diary: "March, 1903: 28th—Soles of both feet swollen and discoloured. Hæmorrhage into tip of right thumb and into left hand. 29th—Swelling of palm of left hand, with pain. Muscle pains severe. 30th—Hæmorrhagic spots in tongue and under right knee. Cough bad. 31st—Cough bad. Muscle pains severe. April: 1st—Pain in both knees acute; no swelling. Hæmorrhage in middle finger of left hand. 2nd—Left wrist swollen and very painful. Knees painful but not swollen." The notes of the symptoms continue in the same style until the middle of June when the troubles ceased for a few days and the patient was able to describe himself as "very well." On the 17th of that month, however, he began to suffer again from pain in the chest and hæmoptysis, and other pains and hæmorrhages soon supervened. In July he improved again and the cough ceased. On Sept. 1st hæmorrhages appeared in both feet and were attributed to the wearing of boots instead of shoes, but within a few days hæmorrhages took place not only in other parts of the lower limbs but also in the palms of the hands. After being free for some months from any very serious trouble the patient was taken ill on the night of Dec. 27th, apparently in consequence of emotional excitement brought on by seeing his father in a severe epileptic fit. When seen on the following morning he was complaining of pain in the lower part of the left chest and a pleuro-pericardial friction sound was heard in that region. He was spitting blood and his pharynx was congested and œdematous. Swelling and ecchymosis were present in the left arm and between the roots of the right thumb and forefinger. A hæmorrhage was detected at the left instep and a certain amount of pyrexia was present. On Jan. 1st, 1904, there were signs of disease at the right apex and the patient seemed dangerously ill. He improved again, but on the 3rd he was *seized with pain in his neck accompanied by* symptoms of shock and he died within an hour.

A post mortem examination was made on Jan 4th at the patient's residence by Dr. Hugh McLaren, assistant pathologist to the Glasgow Royal Infirmary. The general nutrition was fairly good. An extensive ecchymosis was present on the left forearm and upper arm, and after cutting through the skin in this region the hæmorrhage was distinctly seen underneath. A subsequent microscopical examination showed that the extravasated blood was in the interstitial tissue of the muscle as well as in the subcutaneous areolar tissue. The pericardium contained a few ounces of serum. Both ventricles of the heart were distended with blood. The aortic and pulmonic valves were competent. The heart was slightly enlarged, the mitral orifice admitting three and the tricuspid four fingers. The coronary arteries showed some fatty patches but were otherwise healthy. The cardiac muscle was healthy. The right lung was large and emphysematous. The upper lobe was consolidated and had a thick layer of recent fibrin on its surface. It was the seat of miliary tuberculosis and, in addition, contained a small cavity near its apex. The lower lobe was congested and œdematous. The left lung was shrunken and contained numerous miliary tubercles. The liver was the seat of cloudy swelling. The spleen was large and its Malpighian bodies were well marked. Hæmorrhages were present in its substance and the microscope suggested that these were partly in the Malpighian bodies and partly in other parts of the organ. The kidneys were congested and here and there the capsules were adherent. The suprarenal bodies were normal. The wall of the small *intestine was remarkably thin. Recent tuberculous lesions* were found in the bowel, chiefly in the large intestine.

The following is Professor Charles Workman's report on the brain and spinal cord:—

> The brain and spinal cord were preserved in formol and examined by me. The brain presented remarkably healthy characters and was evidently very well developed. Sections of the cord were prepared from various regions and were stained with thionin blue In the cervical region the posterior part of the columns of Goll showed apparently some increase of the neuroglia, while the anterior parts and the columns of Burdach appeared quite normal In the dorsal and l[illegible] sections all the posterior col[illegible]mns appeared quite normal. [illegible] *capillaries especially in the* [illegible]ared unduly numerous and [illegible] them considerably dilated [illegible]erous leucocytes, many of [illegible]ent probably altered blood colouring matter, and t[illegible] colour. In the cervical a[illegible] vessels might be made [illegible] The multipolar nerve cel[illegible] and showed the Nissl's bodies well stained. The pigmented area in these cells did not show so well as is usual, but this was perhaps partly due to the fact that I had hardly carried the decolouration process far enough.

It is evident that the symptoms cannot be explained by the scanty and slight changes which were recognised in the spinal cord. A peripheral nerve which was examined showed no change. Professor Workman examined tissue from the spleen and from the region of the ecchymosis, but after specially staining it for micro-organisms he was unable to discover any.

No cause can be suggested for this remarkable illness. The one fact in the family history which seems to throw light upon it is that the father is an epileptic. Neither the father nor the brother is a bleeder and the patient himself had no excessive hæmorrhage after a tooth extraction In his school days he readily took feverish colds, with cough and expectoration, but he thought they did him no harm. Venereal infection could be excluded. Between the attacks the health was good and the patient could take a considerable amount of exercise. When on holiday in summer he would gain in weight Following his occupation he had been in the East and he once spent a few days in China but he never had malaria, dysentery, or any other tropical ailment. His younger brother, aged 20 years, became ill in the middle of December last, two weeks before the end of a long voyage, with pulmonary tuberculosis, and died in March.

We have not been able to find a report of any other case exactly like the one just described, although a glance through the reports of such cases as Professor Osler has brought together in his papers[1] on the visceral manifestations of [illegible] affinities [illegible] familiar [illegible] *disorder* [illegible] leukæmia, may at once be set aside. Hæmophilia is sometimes associated with hæmorrhages into and around joints but it shows itself earlier in life, runs in families, and does not occur in frequently recurring paroxysms accompanied by severe pain. Moreover, our patient showed no abnormal tendency to bleed when blood was withdrawn for examination or after a tooth extraction. Purpura simplex takes the form of one or more crops of petechiæ, chiefly on the legs, though sometimes on the trunk. As a rule there is no constitutional disturbance and though there may be slight articular pains the actual hæmorrhagic lesions usually give rise to no subjective phenomena. Though wheals and itching (purpura urticans) are occasionally noted, these present no analogy to the severe localised and painful swellings which developed in the present case. In purpura rheumatica there are articular pains with some constitutional disturbance but the articular pains are not attributable to hæmorrhages in or around the joints, and, moreover, there are crops of petechiæ which are not painful In the present case crops of petechiæ were exceptional and large œdematous swellings, which speedily became the seat of hæmorrhage, prevailed. Moreover, purpura rheumatica does not appear in frequently recurring paroxysms involving the most diverse parts of the body as this disease did In purpura hæmorrhagica there are petechiæ as in purpura simplex but here hæmorrhage is the important and serious phenomenon; pain is not a marked feature; there are no tender, œdematous swellings; nor are there paroxysms occurring frequently, during years, with short intervals of health between them Henoch's purpura is characterised by arthritis, purpura, abdominal pain, vomiting, intestinal disturbance, *hæmorrhages from mucous membranes*, and sometimes nephritis and splenic enlargement. In the present case there were seldom petechiæ; the lesions were not specially in the joints, and if seated at the joints were periarticular as well as articular; there was rarely abdominal pain, and the lesions of visible mucous membranes were characterised by swelling much more than by hæmorrhage. Blood actually escaped only from the rectum and the respiratory organs. The whole group of cases included under the designation hæmatidrosis or bloody sweat, bleeding stigmata, and neurotic excoriations may be excluded from present consideration as being characterised by the escape on to the free surface of the skin of a sanguineous or apparently sanguineous fluid. Urticaria in its usual form, characterised by itching wheals of sudden development and transient duration, has no resemblance to the present affection, though wheals did occasionally occur, and a moderate degree of dermographism was recognised in this patient. The more persistent form of that disease, urticaria perstans, is not accompanied by severe pain. In hæmorrhagic urticaria (purpura urticans) a wheal develops in a cutaneous hæmorrhagic lesion, or the converse may be witnessed, or wheals and hæmorrhages may develop side by side In our case there were no wheals as a rule.

The disease presented certain points of resemblance to angio neurotic œdema (acute circumscribed œdema, Quincke's disease, giant urticaria, massive urticaria, &c), in which œdematous swellings develop suddenly in the skin, specially of the face, genitals, and limbs. These may be as large as the palm of the hand and by coalescing may involve extensive areas. But in our case the swellings were not always circumscribed, the visible lesions were the seat of hæmorrhage, and pain was in many of the attacks the first phenomenon In both diseases, however, the swellings of the mucous membranes may cause serious symptoms, as in the larynx, pharynx, and fauces Hæmoglobinuria has been observed in several cases of acute circumscribed œdema but hæmorrhage, either in the skin or from a mucous membrane, though it has been reported, appears to be very exceptional.

The absence in the well-marked attacks of itching, erythema, vesiculation, and desquamation distinguishes the present disease from what Ramsay Smith has described as general angio-neurotic œdema.[2]

The facts of the case just recorded suggest that the disease is a neurosis allied on the one hand to angio-neurotic œdema, though, on the other hand, presenting points of resemblance to a disease which is as likely as not of infectious origin—namely, the purpuric type of erythema. In rare cases of tabes dorsalis small or even considerable subcutaneous hæmorrhages may follow paroxysms of lightning pains, so that hæmorrhage may certainly be due to nervous disturbance. Moreover, in urticaria, into which the neurotic element enters largely, there may be exudation not only of serum but also of corpuscles. It is to be noted that our patient was the subject of factitious urticaria. We may add that Professor Workman, as a result of his anatomical examination of the case, is disposed to accept the view which we adopted after careful clinical investigation and to regard the hæmorrhages as neurotic rather than infectious in their origin.

[2] Angio [illegible]

It should be mentioned that during life numerous remedies were employed for the cure or relief of the disease or its most urgent symptoms but none of them exerted any very noticeable influence. The drugs included antipyrin, ergot, opium, bromide of potassium, iodide of potassium, iron, arsenic, and calcium chloride. Counter irritation in the form of a seton at the back of the neck appeared to do almost as much good as any internal remedy.

Glasgow.

BRACHIAL NEURITIS.[1]

BY CHARLES W. BUCKLEY, M.D. LOND.

THE scanty attention which this subject has received in modern text-books of medicine is remarkable and the references to it in current medical literature are few and far between, although it is as well defined as sciatica and quite as painful and disabling. The same difficulty arises as in sciatica in distinguishing between neuritis and neuralgia, but I wish as far as possible to confine my remarks to the former. It is certainly becoming more common, as is the case with many other affections of the nervous system, but whether this is to be accounted for by a progressive increase in the vulnerability of the nervous structures which appears to be a feature of modern life is a question which I shall not attempt to discuss. The causes are very numerous but the prominent symptom in every case is pain, sometimes sudden in onset, but more often slight and occasional at first and only felt on making certain movements, notably those of raising the arm, but it increases and becomes more continuous with paroxysmal exacerbations; it is dull and varying in character and appears to be greater than in most forms of neuritis. It may be referred to the scapula, especially over the area of the suprascapular nerve, the shoulder-joint, or wrist, with or without the hand, according to the nerves chiefly affected. The form arising from injury is perhaps the commonest and has received the most attention, and I therefore propose to deal with it first and afterwards to point out in what respects those arising from other causes differ from it. This form commonly results from a fall broken by catching at some object, thus throwing the weight of the body suddenly upon the structures at the shoulder joint. The results vary according to the extent of the injury and the nervous symptoms frequently do not show themselves at once but come on gradually, perhaps two or three weeks afterwards when the other symptoms are disappearing. There is marked tenderness over the affected nerves and wasting and paralysis appear in varying degrees, but the reaction of degeneration is rarely present in its complete form though some modification of the electrical reaction is common. In all forms there is some limitation of movement, due more often to pain than to paralysis, and in severe cases passive movement is also limited by changes in and around the joint, in which crackling and grating may be perceived. The cause of these changes has been the subject of much discussion. Barwell[2] points out that in some hysterical subjects crackling, which arises in the subacromial bursa, may normally be perceived on slight movement. Damage to this bursa is very likely to arise in such an accident as I have described, or may arise secondarily from trophic causes, and the crackling may be due to this cause alone, but in severe cases the joint also shares in the trophic effects and synovitis or arthritis results. Jarjavay has demonstrated that if the bursa is torn or otherwise injured it is quite capable in itself of giving rise to coarse crackling and pain, and hence immobility.[3] Duplay, in the only account of a necropsy which appears to be recorded,[4] describes the following changes: (1) chronic subacromial bursitis and subdeltoid cellulitis with obliteration of the bursa and formation of adhesions between the deltoid and the humerus; (2) chronic inflammation of the capsule leading to thickening; (3) periarticular cellulitis internal to the joint leading to formation of fibrous tissue; (4) congestion of the ulnar and internal cutaneous nerves; and (5) atrophy of the deltoid. The circumflex nerve was not examined, but the author assumes that pain on pressure is due to inflammation of the nerve the result of compression and traction by adhesions. There was also a dislocation of the humerus and it seems probable that a good deal may have been attributable to this, for it is difficult to see how such extensive damage could result from a simple strain or bruise of the shoulder, even making the most liberal allowance for trophic effects, but the account throws a good deal of light on the pathology of the symptoms commonly accompanying the severer forms of neuritis. Duplay in illustration quotes five cases of neuritis from simple contusion with similar symptoms and compares them. Certainly very slight injuries may cause synovitis or a nerve lesion with far-reaching effects. Berne supports the view that peri-arthritis is the chief lesion[5] and Vietor puts forward the theory that the shoulder changes are trophic effects from injury to the circumflex nerve, quoting Weir Mitchell in support who says: "Any form of nerve lesion is capable of developing in the joints inflammatory conditions, usually subacute, and which so precisely resemble rheumatoid arthritis that no clinical skill can distinguish between the two."[6] Bowlby differs somewhat from this and says that he has not seen cases of joint injury so severe as Weir Mitchell describes from nerve lesions, but that arthritic lesions of a less severe and more chronic kind are among the most common results of nerve injury.[7]

The evidence I have quoted seems to me sufficient to prove that the effect of the neuritis upon the joint may be very serious and even permanent, although such is not often the case in non-traumatic forms, but cases presenting joint lesions closely resembling those of rheumatoid arthritis are by no means uncommon, and I have dwelt upon this question of trophic joint changes thus fully because I believe that many cases are regarded as rheumatic simply because the joint is affected and the question of injury is overlooked. Simon has recently reported a series of cases of traumatic origin[8] and asserts that some violence is always necessary to the development of brachial neuritis; but in this I cannot agree with him and the analogy of sciatica should be sufficient evidence to the contrary. It must be admitted, however, that sufficient attention may not have been paid in the past to any history of injury, however slight, for the position of the plexus renders it more liable to injury than is the sciatic nerve. I think there is no doubt, however, that the traumatic cases are the most severe of all. The neuritis, as has been mentioned, is sometimes a late result of the injury, and this may mislead as to the cause. Vietor[9] reports a case due to a fall broken by catching at the handle of a door, which showed at the onset pain, weakness of the deltoid, and limited movement; these symptoms improved, but four weeks later the patient suddenly became worse with most intense pain and all the symptoms of a severe neuritis. This late onset was also clearly shown in a case of my own, and equally well by a series published recently by Distin.[10]

Apart from injury gout is undoubtedly the most prominent etiological factor and in many cases the only discoverable cause, while in others it acts merely as a predisposing condition. In men the neuritis may be accompanied by any of the ordinary manifestations of gout, and in women irregular forms are common accompaniments, while in either sex it may be the only symptom and diagnosed as gouty in the light of the family history. Trophic symptoms are rarely marked in this form and the chronic enlargement of the finger-joints commonly present in cases arising late in life are a manifestation of the gouty diathesis rather than a result of the neuritis. The acute forms both in this and the following group are probably in most cases at the outset acute inflammations of the fibrous structures of the muscles recently described by Gowers,[11] and for which he suggests the term "fibrositis." In these cases, which arise commonly after a chill, the onset is sudden with generalised pain and tenderness of the shoulder muscles and the whole arm may be involved so that the patient cannot bear to move in any direction, there are slight pyrexia and loss of appetite, and this acute stage may last for a week or more. The mischief spreads from the muscles to the sheaths of the nerves and often to other fibrous structures in the vicinity, and when the acute condition subsides a chronic neuritis is often left. This course was strikingly evident in one case of my own but I have not often met with it, since cases sent to Buxton for treatment have usually reached the chronic stage or have been chronic from the commencement.

Many cases are termed rheumatic, though probably true rheumatism rarely plays any part in their causation. They often arise from a chill, especially in a gouty subject, and in the majority of cases I am inclined to believe have their origin in a general fibrositis and are acute at the onset like the form I have already described. In two of my cases there were cardiac symptoms; in the first, a case commencing as an acute fibrositis, there was a loud systolic murmur when the patient first came under my observation, a month after the onset, but this, together with the accompanying dilatation, showed marked improvement under treatment and had almost disappeared when he left Buxton a month later. The second case showed slight irregularity with weakness of both sounds but the patient was 69 years of age and had had an attack of influenza during the course of the neuritis, so that *it is not probable that the cardiac condition was due to* rheumatism. With the cases of this type may also be included those occurring in coal-miners, which Charlés has recently described, though there seems in these to be also a possibility of strain as a cause.[12] Many cases occur in women at the menopause, some of which appear to be gouty, while others belong to the class of neuritis occurring in pregnancy and the puerperium, as described by Turney in an exhaustive paper upon the subject.[13] He attributes them to toxæmia and finds that when the neuritis is limited to the arm the median and ulnar nerves suffer the most, otherwise the posterior interosseous is chiefly affected. This differs somewhat from the distribution in other forms, the circumflex being affected by far the most frequently in my experience. The pain is often very severe and wasting may go on to an extreme degree, while, on the other hand, cases occur in which the extent of the neuritis is very limited and the symptoms are slight.

Reflex irritation appears to be responsible, in part at any rate, for a certain number of cases, of which those due to aneurysm are the most important. With this exception they do not call for special mention, but a case which came under my notice, diagnosed as rheumatic, though without very clear evidence, was interesting. There was a lipoma situated in the scapular region from which the pain radiated and it was much worse if the tumour was lain upon or the muscles in relation to it were called into play, the other symptoms being of the usual type. As the improvement was but slow I advised its removal and this was done as soon as the patient returned home. The pain disappeared as the wound healed and the arm is now quite well except for an occasional sensation of coldness and numbness. In most cases, however, a certain degree of psychic concentration of the pain is present and neuralgia often persists as a habit after the removal of the nerve lesion which originally started it. In another case of a lipoma in the same region treatment was sought because of neuralgic pains which, starting from the tumour, radiated down the arm as far as the fingers.

One of my cases was interesting in that it followed an attack of lead poisoning, appearing some six months after the lead was detected. There were none of the usual symptoms of lead neuritis and the case did not differ from the common type, but there was a well-marked lead line with a considerable degree of saturnine cachexia, and the patient was rather emaciated. There were a gouty family history and a few doubtful symptoms of irregular gout. Menstruation was regular and normal, whereas the great majority of cases in women occur after menstrual life has ceased.

To summarise, the prominent symptoms are pain, varying in degree but often very severe when at its height; tenderness of the affected nerve trunks, and of certain cutaneous areas related to them; weakness of certain muscles and limitation of movement, due partly to this and partly to changes in the subacromial bursa, or in and around the joint; trophic changes, rarely severe; and sensory symptoms such as anæsthesia and hyperæsthesia, which are often very slight but often persist after the other symptoms have disappeared. It is certainly open to discussion whether the joint changes when present are in all cases trophic or whether they may not have been primary, the mischief subsequently extending to the fibrous structures in the neighbourhood, which would account for [illegible] cated, but, on [illegible] the shoulder- [illegible] ould probably suffer secondarily to a greater or less extent. Or the fibrous structures of the joint, muscles, and nerves may all be affected at once in an acute attack of fibrositis, with only partial recovery of the joint owing to the trophic influences of the damaged nerves. In my opinion, however, the trophic origin is by far the most common and the joint is more frequently affected in the traumatic cases than in other forms, though this may be partly the result of injury to the joint itself independent of the nerves.

The diagnosis may be difficult; all nerve pains in the left brachial region have, as Gowers has pointed out, a tendency to resemble anginal pain and to be accompanied with cardiac distress; aneurysm is a possible source of error and tumours of the cervical spine or of the bones of the shoulder may by *pressure on the nerve closely simulate neuritis or cause* neuralgia, while lesions of the cervical cord must not be forgotten. Time will not permit me to discuss the differential diagnosis but the influence of movement, the presence or absence of tenderness, and, in some cases, the use of the Roentgen rays are important aids.

As to the prognosis, the duration is probably never less than three or four months and may extend over a year or more. The older the patient the more chronic the case is likely to be, while much depends on the degree of rest which the parts obtain. Relapses occasionally occur and recovery is often incomplete, the limb remaining weak, with occasional tingling pains or numbness, while there are frequently adhesions left in the shoulder-joint after a severe attack.

With regard to treatment, in cases commencing acutely, whether as part of a general fibrositis or as a simple neuritis, rest in bed is necessary at first with purgation and treatment suitable to the general condition; colchicum and alkalies may be useful in gouty subjects or salicylates if the case is of rheumatic origin. In the acute cases I have found aspirin with or without phenacetin of much value and mesotan for external application is often very useful. Poultices and hot applications generally give relief to the pain and where they fail ice is sometimes of use. I have found the coal-tar analgesics when given in regular and sufficient doses more generally useful than opium or its derivatives for the relief of pain, and in this the majority of recent writers agree, but in the most severe cases morphine becomes necessary. When the acute stage is past, rest to the affected limb is still, as in those cases chronic from the first, of the utmost importance; this can usually be secured by the use of a sling but it is sometimes better to bandage the affected limb to the side. In the chronic cases of gouty origin alkalies and iodide of potassium are sometimes of value and chloride of ammonium may be tried but otherwise drugs, with the exception of analgesics, are of little use and, considering the long duration of the majority of cases, other measures for the relief of pain are desirable whenever possible. I have found the greatest benefit in this respect from the free use of blisters along the affected nerve trunks or over the tender points, while subsequently, or in cases in which the pain is less severe, galvanism has an anodyne effect and both undoubtedly exert a beneficial effect upon the general course of the disease. Other forms of electricity are of much less value, being, as Lewis Jones ("Medical Electricity") has pointed out, chiefly of use in those cases in which neuralgia persists as a habit after the disappearance of the nerve lesion which *originally* caused it. Faradism and the sinusoidal current are, however, of use in the treatment of the wasted [illegible] and some authorities have found high frequency currents benefit. Massage, in my own opinion, must never be used as long as the nerves are acutely inflamed; later it is of value for the removal of the inflammatory effusion in the nerve trunks and especially in traumatic cases with effusion into and around the joints when it may often be advantageously combined with radiant heat, but if it causes any marked pain I am strongly of opinion that it does more harm than good. In the rheumatic and gouty cases a course of treatment at Bath or Buxton is of great benefit and the majority of cases find relief from the mineral baths, vapour baths, and hot douches which are a feature of the treatment at both places. The diet and digestion often call for attention and tonic treatment by drugs and change of air is generally desirable in view of the debilitating effect of the long-continued pain. In choosing a place to which the patient may be sent it is important to remember that the sea does not suit many cases and a bracing inland climate is more generally beneficial, though a clay soil should be avoided if possible. The combination of such a climate with the advantages of balneological treatment renders Buxton especially suitable for these cases. As is usually the case in such chronic and obstinate conditions, the number of remedies that have been suggested is legion but I have only advocated those which I have personally found beneficial.

Buxton.

INTRACRANIAL RESECTION OF THE SECOND DIVISION OF THE FIFTH NERVE FOR EPILEPTIFORM NEURALGIA.[1]

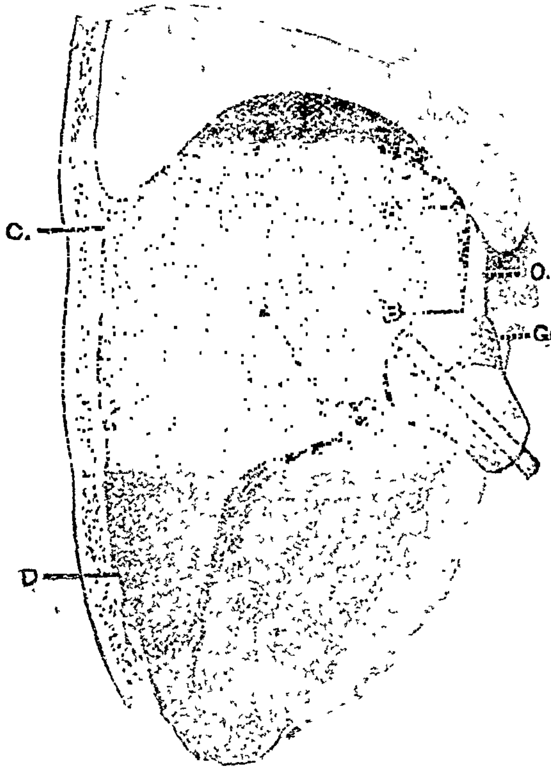
By J. HUTCHINSON, JUN., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

SOME three years ago, in a paper on excision of the Gasserian ganglion, I advanced the proposal "that the so-called excision of Meckel's ganglion (always a very difficult and uncertain proceeding involving disfigurement of the face) should be given up in favour of intracranial division of the superior maxillary trunk just above the foramen rotundum."[2] The recommendation was based on the following considerations:—

1. The more central the operation, the nearer to the brain, the more certain is the prospect of permanent cure. In almost every case of peripheral operation, including removal of Meckel's ganglion, the neuralgia has returned after an interval of a few months or years.
2. The surgeon who works through the walls of the antrum to the pterygo-maxillary fossa is greatly hampered by the depth of the wound and by hæmorrhage from the internal maxillary artery. He may be successful in defining the trunk of the superior maxillary nerve in the upper part of the fossa, but he is very likely to fail.
3. A depressed scar in the middle of the cheek is much more disfiguring than one hidden by the scalp in the temporal region.

In the middle fossa of the skull the whole of the superior maxillary trunk, before it has given off any branches, can be exposed. Here it can be not only divided but a considerable portion of it can be excised so that there will be no chance of subsequent union. The amount of the nerve available at this point for excision varies somewhat in different subjects, but from one-third to half an inch can be resected. The accompanying figure will make this plain. The trunk should be divided just at the foramen rotundum and again where it leaves the Gasserian ganglion, as shown at A B Cases in which such an operation is justified are not numerous and it was only about a year ago that one presented itself to me.

A ship's officer, nearly 60 years old but of fine constitution, had suffered for several years from intense pain in the right cheek and the upper jaw. The neuralgia was typically epileptiform, the attacks becoming more and more frequent during the last four years. He had had a number of teeth removed without the slightest relief and medicines were equally unavailing. He struggled on with his duties on board a Cape liner and about Christmas, 1902, he consulted Sir Frederick Treves with regard to operative measures who kindly sent him to me with a note suggesting the removal of Meckel's ganglion and the infra-orbital nerve. The distribution of the neuralgia was always the same and the parts were very tender, though during an attack some relief was obtained by the patient violently grasping the tissues of the cheek. The lower eyelid, both sides of the cheek, the palate, and the gums on the right side formed the area involved. Lacrymation and congestion of the right eye were frequent. It might be suggested that exposure on deck to wind and wet was a predisposing cause of the neuralgia but the attacks were equally severe when he was on land and they occurred both by day and night. He had the aspect of great suffering and depression.



Intracranial resection of the superior maxillary nerve. A B, Portion of nerve to be excised. C D, Wall of temporal fossa cut away in the operation. O D, Ophthalmic division. G, Gasserian ganglion.

My friend Mr. T. Crisp English assisted me at the operation, which was performed with the patient fixed in a dentist's chair in order to lessen the trouble from venous hæmorrhage. A horseshoe flap was turned down from the temporal region, having its base at the zygoma, the flap including part of the temporal muscle and the pericranium. With a large trephine and cutting forceps the subjacent bone was removed and the dura mater was exposed. As in the operation for removal of the Gasserian ganglion the dura mater and the temporo-sphenoidal lobe were then carefully pushed upwards and inwards, making for the foramen rotundum as the landmark. (In this respect the two operations differ, as in dealing with the Gasserian ganglion the foramina spinosum and ovale are first sought for.) Considerable difficulty was met with owing to the thin and fragile character of the dura mater and some cerebro-spinal fluid escaped. Ultimately the trunk of the superior maxillary division and part of the Gasserian ganglion were thoroughly exposed, a broad spatula of soft metal being used to retract the dura mater and the brain. The whole of the nerve was then removed, a small drain was subsequently inserted, and the flap was sutured in position. None of the bone removed was replaced. Primary healing followed and no complication of any sort occurred. The patient returned a month later to his duties and has made regular ocean voyages ever since.

I have waited 12 months before reporting the case in order to ascertain that the relief is permanent and I am glad to state that he has not had the slightest recurrence. The anæsthesia is most marked over the cheek and the right superior maxillary bone; it involves also the soft palate and

---

[1] A paper read at a meeting of the Clinical Society of London on March 11th, 1904.

[2] Transactions of the Medical Society of London, vol. xxiii.

has practically filled up, and there is, of course, no paralysis of masticatory muscles on that side such as follows removal of the Gasserian ganglion. I am confident that no recurrence is likely to take place.

It would be erroneous to suppose that the operation is an easy one: the depth of the nerve trunk (three centimetres or more from the wall of the temporal fossa) and the troublesome oozing in a narrow space where it is essential to see and to define a nerve-trunk of small size prevent this. But having had the opportunity of assisting my colleague Sir Frederick Treves in several operations on Meckel's ganglion I can safely assert that the intracranial route is at least as easy as the facial one and without any doubt it affords the more certain access.

It will be remembered that the superior maxillary nerve immediately on entering the pterygo-maxillary fossa gives descending branches to the palate and bone with internal branches to the cavity of the nose. It is easy to follow up and to remove the infra-orbital nerve from in front but it is very difficult to remove the trunk and all its branches in the fossa. Moreover, even if this is accomplished the evidence is strong that recurrence of the neuralgia is only a matter of time. In Sir Frederick Treves's five cases it recurred within 12 months in two, a third patient died (from cancer) within six months of the operation, and in the remaining cases recurrence was observed in two and three years respectively. Mr. T. F. Chavasse collected 22 cases of what is often termed Carnochan's operation; in only three was the relief stated to be lasting. With regard to operations on the Gasserian ganglion properly carried out (this may be emphasised without going into details here) the evidence is conclusive that the neuralgia is permanently cured.

There are other methods of approaching the superior maxillary trunk which I venture to think compare most unfavourably with the temporal route. In Professor Lücke's operation the masseter muscle is divided, the zygoma is cut through, and an extensive scar is left on the side of the face. The zygoma may not unite again and movements of the lower jaw may be much interfered with. Nussbaum and Billroth employed osteoplastic resection of the upper jaw, while Kocher and others used methods involving a temporary resection of the outer orbital wall. Not one of these methods or their modifications afford access to the trunk where it comes off from the Gasserian ganglion. In Sir Frederick Treves's words: "These various measures are all needlessly severe and involve wounds of great and unnecessary magnitude."

It is well known that in cases of epileptiform neuralgia of the fifth nerve one, two, or three divisions of the nerve may be involved. In some patients the pain is mainly limited to one division, usually the inferior or the superior maxillary, with radiations into the ophthalmic branches or even the cervical plexus. Experience has shown that a thorough operation on the central part primarily involved will almost always cure the lesser and more widely distributed neuralgia. Supposing the inferior maxillary division to be alone or mainly affected it is open to question whether an intracranial removal of the lower part of the ganglion and inferior maxillary trunk would not be preferable to the elaborate operation usually performed below the foramen ovale. The conditions here are not so favourable, however, as exist in the superior maxillary trunk where about half an inch of the nerve can be exposed and removed. Codivilla, an Italian surgeon, has, however, performed it twice with success, his first case being in 1897. When both second and third divisions are mainly involved I am sure that removal of the lower half of the ganglion, leaving the ophthalmic division intact, is the best operation. As a series of cases has shown, going back from two to seven years, no recurrence of neuralgia need be feared in the ophthalmic part that has been left intact. But where the superior maxillary division alone is concerned the operation described may be advocated in preference either to Carnochan's method or the more complete operation on the Gasserian ganglion itself.

(Note.—After the foregoing paper was read at the meeting of the Clinical Society Mr. Stanley Boyd related a case in which he had—about the same time as myself—performed intracranial resection of the second division of the fifth nerve for epileptiform neuralgia limited to that distribution. The result had been complete relief for about a year, at the end of which time slight neuralgia was again reported, though its localisation was uncertain.)

Cavendish square, W.

NOTES ON A CASE OF MYELOPATHIC ALBUMOSURIA.

BY R. CATHCART BRUCE, M.D. EDIN.,
KENNETH F. LUND, B.A. CANTAB., M.B. LOND.,
AND
P. PERCIVAL WHITCOMBE, M.B. LOND., M.R.C.S. ENG.

CASES of myelopathic albumosuria are sufficiently rare to justify our reporting in full the following one which first came under our care in December, 1902.

On Dec. 30th the patient, a female, aged 51 years, was crouching down before the fire when "she turned faint, felt something give way in her thigh, and fell over on the floor." On examination it was found that she had sustained a simple fracture of the left femur at the junction of the middle and lower thirds with an unusual and peculiarly dry grating crepitus. The fracture was put up in the usual way and at the end of two months was firmly united with about one inch of shortening and a large amount of callus. A week after the setting of the fracture, in January, 1903, as the nurse was raising the patient in bed with one arm under the left axilla she felt a distinct crack and it was found that the left clavicle had become fractured near the acromial end. This fracture never united and a false joint formed with a swelling of the size of a hen's egg and semi-fluctuating in character over the seat of fracture. Three months later the patient was well enough to be removed to the country and while entering a carriage experienced a sharp pain in the left side of her chest. On arriving home she was put to bed, where a medical man found that she was suffering acute pain in the chest wall, with a temperature of 105° F. The diagnosis given to the relatives was "pleurisy," but, as the necropsy revealed, the condition was more probably due to a spontaneous fracture of the rib owing to muscular exertion. During July and August the patient was suffering from marked and increasing anæmia, emaciation, and lassitude. Attacks of vomiting and diarrhœa were frequent in spite of care in diet. The quantity vomited was considerable, amounting to from one to four pints, and consisted of partially digested food which was never blood stained. The attacks occurred suddenly, without pain or effort or previous nausea. The loose motions were extremely offensive. On Sept. 13th the patient when in bed fractured her left humerus at the junction of the lower and middle thirds when endeavouring to reach something lying beneath her. This fracture did not unite as she rapidly became weaker and wandering in her speech, finally passing into a kind of stupor, until the evening of Sept. 27th, when she died.

Previous history.—When about 13 years of age the patient was laid up for a period of two years with lateral curvature of the spine which became permanent. There was no Pott's curvature or disease of the vertebral bodies. She never had any other serious illness. For the last 20 years, owing to a change in her circumstances and straitened means, she had partaken of a very spare diet, with little meat and much bread and tea. During this time she was employed as a journalist and though energetic and active did a great deal of literary work at her desk. In February, 1902, she fell in the street suddenly and without apparent cause. In her own words, she "felt giddy and fell on her right hip"; she was picked up and went home in a cab and except for feeling somewhat shaken was none the worse after two days in bed.

General symptoms.—When first seen the patient, who was always small and of a spare habit, presented the appearance of anæmia and general debility. She complained at various times of pains in the chest, the back, the right side, and the left hip. They were often severe, neuralgic in character, and nothing seemed to relieve them. They varied in intensity and situation and it is noteworthy that she never complained of any of the pains after the fracture of the left arm. During the eight months she was under observation her weakness increased and became at last extreme, with marked anæmia and emaciation. No enlargement of the bones was perceptible at any time during the illness. During the last month or six weeks the temperature was generally above normal, of hectic type, varying from 99° to 102° in an irregular manner, the pulse-rate being correspondingly quickened.

Family history.—There was nothing remarkable in the family history, as the patient's parents and grandparents lived to old age and her brothers and sisters are all healthy.

Examination of the urine.—It occurred to one of us (K. F. L.), who recalled a case recorded by Dr. T. R. Bradshaw of Liverpool, that this was an instance of albumosuria, as the following analysis of the urine proves. It was pale straw in colour, at times syrupy in consistence, and forming an abundant and persistent froth on shaking; the odour was peculiarly aromatic, which was also perceptible latterly in the patient's breath. It had a specific gravity of 1019–1022 and varied in amount from 80 to 120 ounces in the 24 hours. The reaction was neutral or faintly acid. On heating in a test tube a precipitate formed which dissolved on boiling. When treated with cold concentrated nitric acid a dense curdy precipitate formed, which entirely dissolved on boiling and reprecipitated on cooling. When treated with cold concentrated hydrochloric acid a precipitate formed sometimes slowly, sometimes at once, which dissolved on boiling and reprecipitated on cooling. With a few drops of acetic acid and the addition of potassæ ferro-cyanide (10 per cent. solution) a turbidity appeared, but only on standing for some time. This precipitate (and that obtained by heating) was soluble in caustic soda or caustic potash. This solution reacted to nitric acid in the same manner as the specimen of urine before the addition of caustic soda or other reagent. The amount of precipitate present was considerable, the dense precipitate formed after addition of picric acid or nitric acid occupying four-fifths of the column of urine after standing for 24 hours. A few oxalate crystals were occasionally present. The urea was estimated as 4·15 grains per ounce. Sugar was absent but the specimens always gave the biuret reaction. In this connexion we may note that Dr. Bradshaw says:[1] "Contrary to what is generally taught I am convinced that the biuret reaction affords no indication by which we may distinguish between globulins and albumins on the one hand and albumoses and peptones on the other." A specimen of the urine was sent to Dr. Bradshaw who very kindly confirmed the tests and reported that "the proteid in the urine sent to him coagulated at 58° C. and almost entirely dissolved on boiling; but that on the other hand the precipitate with concentrated hydrochloric acid was much less dense than usual."

Necropsy.—A complete post-mortem examination was not permitted but a partial examination was made 24 hours after death. Cadaveric rigidity had not then set in and there were no post-mortem ecchymoses. The abdominal wall already showed signs of commencing decomposition. The sternum and rib cartilages, the left clavicle, and portions of the left humerus were removed. The lungs and heart appeared pale but normal. There was no fluid in the pleural cavities and no sign of recent or old-standing pleurisy. There was thickening of one of the ribs on the left side which suggested recent fracture. After removal of the fractured portion of the humerus about six ounces of a pale pink blood-stained fluid, imparting a gluey or soapy feeling to the touch, filled the cavity thus made and was reserved for examination. It apparently escaped from the sawn ends of the humerus.

Pathological report.—The tumours consisted of a round cell growth, richly supplied with blood-vessels, the connective tissue sheaths of which could be readily seen. The cells of the mass consisted of a nucleus nearly of the size of a red blood corpuscle, deeply stained by hæmatoxylin and showed only a small mass of protoplasm. The protoplasm so far as we were able to say was agranular, and Mann's stain, when used both by the long and short method, did not show anything that we were able to recognise similar to the "red bodies" described by Muir. Practically the mass had the greatest resemblance to a round-cell sarcoma. The microscopical appearance closely resembled that described by Bradshaw and Warrington in 1899 but differed in certain points from that described by Parkes Weber with Muir's report.

Dr. Bradshaw kindly examined the fluid taken from the arm after sawing through the bone and reported that he looked chiefly for indications of the presence of the Bence Jones albumose. He says: "It is very difficult to detect it when mixed with a large amount of other proteids. I found (*a*) that some coagulation takes place on heating a watery extract of this material to about 60° C.; (*b*) that the watery extract (or solution) gives a well-marked albumose reaction on boiling with nitric acid; and (*c*) that when the solution is boiled with a little acetic acid and sodium chloride and filtered hot the filtrate becomes slightly turbid on cooling. These reactions, as far as they go, suggest the presence of albumose. I have, however, found a slight coagulation at 60° C. on heating a solution of normal bone marrow." We can only say that the analysis, particularly test (*b*), suggests the presence of albumose or some closely allied body.

Treatment.—We have said nothing as regards treatment because we discovered nothing that had any power to arrest the course of the disease. Treatment of any sort has so far proved ineffectual and we have not been able to discover any suggestion as to the course to pursue in such cases. Hæmoglobin, liquid peptonoids, iron, phosphates, &c., were all tried in rotation with equally unsatisfactory results. The vomiting generally ceased spontaneously and seemed to be due to dilatation of the stomach owing to inertia, as no pain, tumour, or tenderness was present. The diarrhœa, which, as we remarked before, was accompanied by peculiarly offensive motions, was checked by pilula plumbi cum opio with salol in cachets.

Remarks.—The points of resemblance to other cases recorded, apart from the condition of the urine, are: 1. The fragility of the bones. 2. The extreme anæmia and lassitude. 3. The pains of neuralgic character, varying in intensity and situation, aggravated by movement, and accompanied by local tenderness. 4. The presence of a semi-fluctuating tumour over the acromial end of the clavicle in connexion with the false joint. The peculiarities of the case are: 1. The fractures occurring solely on the left side. 2. The occurrence of the disease in the long bones, humerus and femur; no disease in cranial bones. 3. The absence of any prominences on the bones. 4. The sharp grating crepitus of the fractures resembling that produced by old dried museum specimens. 5. The fact that a firm union took place in one of the fractured bones—viz., the femur, although infiltrated with disease of a malignant nature. 6. The female sex of the patient. Most recorded cases have been in males.

ON THE TREATMENT OF CANCER WITH RADIUM BROMIDE.

BY H. G. PLIMMER, M.R.C.S. ENG., F.L.S.

IN November last Lord Iveagh generously placed at my disposal some radium bromide, with the request that I would investigate its effects upon cancer. The staff of the Cancer Hospital allowed me to make use of the following cases, so that I was enabled to follow the effects of the action of radium more or less completely on 17 cases which I have tabulated in a form giving a general view of the cases and the extent of the treatment. The amount of radium bromide used for these cases was 30 milligrammes and it was inclosed in a vulcanite capsule covered with talc. It was made by the Braunschweig Chinin Fabrik.

It will be noticed that this series of cases consists entirely of carcinoma, many of the cases being in a very advanced condition. The diagnosis was confirmed in all of them either by the examination of the primary growth or by the excision of a nodule. The individual exposures varied from 40 minutes to five minutes; and the capsule containing the radium was placed directly on the nodules or lumps, the only thing intervening between the radium and the skin being the talc top of the capsule. I left the cases for a month after the exposures and then examined them to see in what condition they were. The effects in all the cases were negative, either no change or an increase in the size of the nodules. Cases 3, 14, and 17 were all about to slough when they came for treatment, and there is nothing whatever to indicate that the sloughing was in any way hastened by the treatment. The effect on the skin varied in the different cases; an exposure of ten minutes was generally sufficient

TABLE OF CASES OF CANCER TREATED WITH RADIUM BROMIDE.

No.	Sex.	Age.	Nature of cancer.	Total time of application of radium.	Between dates of—	Longest and shortest time of application.	Skin.	Remarks.
1	F.	53	Three nodules on the right chest, secondary to cancer of the breast.	20 minutes.	Nov. 17th and 27th.	5 minutes.	Reddened.	The patient died on Dec. 31st. A nodule was removed on Nov. 25th to see what effect had been produced.
2	F.	42	Two nodules on the left chest, secondary to cancer of the breast.	10 minutes.	On Nov. 17th.	5 minutes to each nodule.	,,	Nodules have ulcerated and the patient is considerably worse.
3	M.	40	Sloughing epithelioma of the lip.	10 minutes.	Nov. 18th and 20th.	5 minutes.	Broke down two days after the last application.	This was a raised nodule in a diffuse epithelioma of the lip which was soft at the time of application.
4	F.	28	Multiple nodules on the chest, secondary to cancer of the breast, and a gland above the clavicle.	2 hours 50 minutes to nodules and 45 minutes to gland.	Nov. 19th and Jan. 25th.	30 minutes; 5 minutes.	Blistered and scabbed.	The gland at first seemed softer but did not diminish in size. A nodule was removed for diagnosis.
5	F.	40	Ulcerated contracting scirrhus of the breast.	25 minutes.	Nov. 19th and Dec. 22nd.	5 minutes.	Reddened.	The patient died on Jan. 23rd.
6	F.	44	Recurrent growth of the breast in and about the scar.	11 hours 55 minutes.	Nov. 23rd and Feb. 9th.	30 minutes; 5 minutes.	Blistered and scabbed.	The nodules increased rapidly in size.
7	F.	44	Gland deep in the axilla.	36 minutes.	Nov. 24th and Dec. 18th.	8 minutes, 5 minutes.	Reddened.	No change.
8	F.	80	Moveable lump in the right breast about three inches by two inches.	14 hours 25 minutes.	Nov. 24th and Feb. 10th.	40 minutes; 5 minutes.	Blistered and scabbed, at first blackish in colour, later white and scaly.	This patient showed no sign of improvement in the primary growth and an axillary gland enlarged to a good size during treatment.
9	F.	64	Diffuse mass of secondary ulcerated cancer in the right axilla.	1 hour 30 minutes.	Nov. 24th and Dec. 19th.	5 minutes.	Very thin and red before treatment.	The patient died on Jan. 11th.
10	F.	54	Cicatrix adherent to the ribs, with small nodules in it.	3 hours 45 minutes	Nov. 28th and Feb 1st.	30 minutes; 5 minutes.	Blistered early.	No change.
11	F.	53	Diffuse mass of secondary cancer in the right axilla.	2 hours 35 minutes.	Dec. 1st and 19th.	10 minutes; 5 minutes.	Very red and angry before treatment.	The patient thought she could move her arm better but there was no change in the growth.
12	F.	63	Small nodules beneath the skin between a cicatrix and the clavicle on right chest.	1 hour 20 minutes.	Dec. 7th and Jan. 27th.	5 minutes.	Blistered and scabbed.	No change.
13	F.	60	Secondary growth in the axilla and gland above the clavicle.	3 hours 15 minutes.	Dec. 10th and Feb. 4th.	15 minutes; 5 minutes.	,,	The patient thought she could move the arm better but no change in the growth was effected.
14	M.	53	Fungating mass below the jaw, secondary to epithelioma of the lip.	15 minutes.	On Dec. 17th.	15 minutes.	Sloughing.	The mass sloughed out a few days after.
15	F.	52	Two very small subcutaneous secondary nodules near cicatrix of the breast.	3 hours 10 minutes.	Jan. 13th and Feb. 10th.	40 minutes; 30 minutes.	Blistered.	There was no change in the nodules and a new one appeared during treatment.
16	F.	60	Secondary glands in the axilla.	1 hour 30 minutes.	Jan. 18th and 25th.	30 minutes.	,,	No change.
17	F.	48	Large mass of secondary growth over the sternum, about to slough.	1 hour 10 minutes.	Jan. 21st and 22nd.	40 minutes; 30 minutes.	Reddened.	The growth began to slough.

to produce blistering, and then scabbing, and under the scabs there was found a very slowly-healing ulcerated surface. The radium had apparently no effect with regard either to causing or to relieving pain and the irritation of the blisters was slight.

From three of the above patients who died some nodules which had been treated were excised and subjected to a careful microscopical examination. In all these cases no change was found either in the cancer cells or in the fibrous tissue and none were degenerated. There appeared to be an increase in the amount of the subcutaneous round-celled exudation which was greater in amount in those nodules which had been more recently treated, but the irritation of the skin would sufficiently account for this. On the other hand, Dr. Apolant, writing from Professor Ehrlich's laboratory, records[1] some very satisfactory and striking results obtained by treating very rapidly growing nodules of inoculated cancer in mice with radium. The nodules decreased remarkably in size, but it was apparently difficult to get rid of the last bit of the nodule, probably on account of fibrous changes. These results are much the same as those obtained by Professor Exner in Vienna in a case of melanotic sarcoma with multiple rapidly growing nodules in the skin. It appears as if the emanations from radium can only act upon young and rapidly growing cells and that older cells, especially if surrounded by fibrous tissue, are less and less easily affected, and if there be an excess of fibrous tissue the cells are not at all affected.

Lister Institute of Preventive Medicine, S.W.

GENERAL LYING-IN HOSPITAL, YORK-ROAD, LAMBETH, LONDON, S E.—An entertainment will be given in the small Queen's Hall, Langham-place, London, W., on the evening of Thursday, May 26th, the proceeds of which will be devoted to defray the cost of the new dining room for midwives and nurses and the new sitting room for nurses now in course of construction at the hospital. The entertainment will cc
bazaar will also
Friday, July 8th,
to provide funds
and nurses in con...
be handed to a ladies' committee which is now being formed to assist convalescent patients requiring the benefit of a short rest in the country.

THE SITE OF REFERRED PAIN IN VISCERAL DISEASE FROM AN EMBRYOLOGICAL STANDPOINT.[1]

By W. M. WILLOUGHBY, B.A., M.B., B.C., D.P.H. CANTAB.,
ASSISTANT MEDICAL OFFICER, PORT OF LONDON SANITARY AUTHORITY.

FROM the clinical experience of many observers, and from a consideration of anatomy morbid and otherwise, the pains and hyperæsthesias arising from the various viscera in morbid states have been located in various regions of the parietes. I propose to approach the subject of the location of pains referred from the viscera from an embryological standpoint, and consider that many phenomena at present clinically obscure are thus elucidated.

That a viscus unilateral in origin and development has a unilateral nerve-supply is axiomatic—e.g., the ureter. It is *just as clear that viscera bilateral in origin*, formed by fusion of lateral structures, retain in each half their lateral innervation—e.g., the uterus. If one considers the history of some viscera hereafter referred to as median in origin, bilaterally symmetrical halves with bilaterally symmetrical nervous rudiments are traceable; a median diverticulum from such an organ will partake equally of the right and left halves and of their right and left innervation; for example, the foregut and common bile-duct. Given that the organs retain throughout their development their primitive or embryonic nervous connexions, I suggest as a working hypothesis: 1. That viscera lateral in origin and development if they give rise to pain or hyperæsthesia at all refer this to their own side of the body wall. 2. That viscera bilateral in origin but asymmetrically developed refer their pains and hyperæsthesias predominantly to that side of the body from which the predominant element, be it right or left, is derived. 3. That viscera *median* in origin give rise to pains and hyperæsthesias on both sides of the midline in states affecting both sides of the viscus, or if affected on one side on that side, near the midline, to which the half of the viscus in which the lesion is situated originally belonged. 4. That viscera lateral and bilateral in origin and developing symmetrically give rise to pain on either or both sides according to the situation of the lesion or other morbid state. Viscera illustrating these origins, the referred pain of which is discussed below, are: (1) ureters, testicles, ovaries, Fallopian tubes, and the aortic arch except the ascending portion; (2) ascending aorta and heart; (3) trachea, œsophagus, stomach, duodenum, bile-ducts, small intestine, appendix, large intestine, rectum, and bladder; and (4) uterus.

I will not go over ground already well covered by many observers but simply state their findings that these structures are themselves entirely insensitive to pain, and will first discuss the pains referred from the diseased aortic arch because pains whose seat is most varied afford most interest, whose cause is least known need most elucidation, and whose explanation if acceptable will give greatest support to the hypothesis.

The embryology of the aortic arch subdivides itself into that of the ascending aorta and that of the remainder. The transverse portion beyond the innominate artery and the descending arch have normal origin in entirely left-sided structures—the vessels of the left visceral arches, and according to hypothesis should have their pains referred entirely to the left side of the body. The ascending aorta has a complicated development from the bulbus arteriosus which in its turn has a simple development as being the upper portion of a tube formed by the fusion of two symmetrically placed right and left ventral vessels. Could we but estimate how much of the ascending aorta is formed from the right element of the bulb and how much from the left, we might suggest what proportion of the referred pains of acute and chronic aortitis in this situation ought to be felt on either side of the body.

The septum superius has origin from above downward, from between the fourth and fifth left branchial vessels where it is situated antero-posteriorly; at the level at which the semilunar valves *will later be developed, the plane of the* septum cutting the bulbus arteriosus into ascending aorta behind and pulmonary artery in front is transverse. The anterior border of this septum, in fact, has passed spirally from left to right through 90°. The bulbus arteriosus is the portion of the fused ventral vessels which most retains its primitive position, being anchored as it were above by the paired vessels passing to the branchial arches. Thus we can estimate that of the right and left elements forming the bulbus arteriosus more of the right element has been cut off in the longitudinal division which takes place to form the ascending aorta than of the left, especially just below the level of the innominate artery, while at the point of divergence of aorta and pulmonary artery the right and left primitive elements take equal share in aorta formation.

By hypothesis, therefore, pain and hyperæsthesia arising from aortitis, acute or chronic, just above the aortic ring should be referred to right and left of the midline; arteritis higher in the ascending aorta should give pain and hyperæsthesia mostly to the right. As we have seen, the arch beyond the innominate artery should give rise to entirely *left-sided* pain. The common form of arteritis, however, and its effects are not usually circumscribed but are found in lessening degree from the aortic ring onwards, the inflammation being started by a cause acting equally throughout the whole aorta but confirmed by the systolic shock and pressure felt in diminuendo along the artery. Seldom will atheroma be found limited to the neighbourhood of the aortic ring, yet more seldom in patches more remote while the ring remains free.

What is angina pectoris? Angina is a pain felt in the parietes, referred there from a centre in the cord irritated by afferent impulses passing along one or more visceral nerves of the first, second, third, fourth, and fifth dorsal, and perhaps some lower cervical segments. Whence do these afferent visceral nerves acquire the impulses which render their centres irritable? I quote the Regius Professor of the University of Cambridge, whose Cavendish lecture on Disease of the Ascending Aorta has so broadened the horizon in the etiology of angina pectoris. He says: "We may guess that the relation of the fibrous tissue to the nervous tissue of and about the ascending aorta may be the determining factor of pain in inflammation, acute or chronic, of these parts." So we have impulses starting in and about the ascending aorta going to the right and left segments of the cord, impulses from the transverse and descending arch (I have said that aortitis is rarely limited) irritating left-sided portions of the cord, and all that is wanting is a stimulus to start the explosion which is to run along the prepared train and give rise to the sensations so well known.

Burney Yeo in his "Manual of Medical Treatment" inclines to the view that heightened blood pressure is a result rather than a cause of anginal pain, but we can easily imagine that a slight rise of pressure—due to emotion, for instance—is a cause of sufficient afferent stimulus to initiate katabolism of nerve substance already rendered unstable, and that the effect of the resultant pain thus initiated may be a still further rise of blood pressure to the establishment of a vicious circle. However this may be, angina is felt in the right- and left-sided distribution suggested by our hypothesis, radiating more often to the left in accordance with the preponderating left embryonic origin of the seat of the causative lesion, most frequent, persistent, and intense in a bilateral sphere about the junction of the corpus and manubrium sterni, just as the origin of the first part of the ascending aorta is most active in mischief and is bilateral in origin, often radiating to the right even as the upper part of the ascending aorta has a preponderant right-sided origin. So much for the pain of angina. Burney Yeo in his "Manual of Medical Treatment" gives pictures showing hyperæsthetic spots in[2] "aortic disease." I suggest that these pictures represent the hyperæsthesias of an aortitis in which disease of the aortic ring is an incident: indeed, so-called aortic disease and aortitis are in many cases inseparable etiologically and combined clinically. If the brunt of the disease has fallen on the aortic ring and its immediate environment, we should by hypothesis expect pains and hyperæsthesias referred to either side of the midline.[3]

As to the left location of pains and hyperæsthesias which clinically with certainty may be traced to morbid conditions of the heart, we find that, as for the anterior end of the fusion of the ventral vessels which forms the heart, the paired visceral arches form an anchor and are a guide to its constitution, so for the posterior end the paired umbilical and vitelline veins mark off the primitive right and left portions of the common auricular chamber. This chamber opens by an aperture, slit-like and transverse, into the ventricle: of this aperture the walls of the left end are derived from the left element and those of the right end from the right element. Later this orifice becomes divided by the ventricular septum into left and right portions, the left forming the mitral orifice, the right the tricuspid orifice. At this point we have the original left and right elements preserved in their original relation. The brunt of the commoner morbid states of the heart, by reason of the higher pressure within the left ventricle in systole, falls on the left side; in particular is the wall of the left auriculo-ventricular orifice affected and we have seen that this can be traced to be a primitive left structure. By hypothesis, therefore, pain and hyperæsthesia of mitral disease should in all cases be referred to the left side of the body wall.

---

[1] Thesis for the degree of M.D.

[2] Burney Yeo: Manual of Medical Treatment, part ii., chapter v., Fig. 14.

[3] Figs. 13 and 14, loc. cit.

Clinically this is found to be the case. I may refer to an excellent diagram of left sided hyperæsthetic spots in a case [illegible] Yeo's "Manual of Medical [illegible] nany of these spots depicted [illegible] rent visceral nerves from the [illegible] the septa of the common ventricular chamber of the fœtal heart develop in such a way as by no means to separate the original right and left elements, I am unable to suggest in what proportion the elements are embodied in either ventricle or to suggest that some of the spots may be due to myocarditis of the left element; nor does the morbid anatomy of mitral disease, except in a later stage, permit one to consider in its connexion tracts of the heart wall remote from that originally left-sided structure the wall of the mitral orifice. As I have said, the common auricular chamber preserves the right and left positions of its constituent elements, and though the auricular septa do not seem exactly to re-divide those elements, yet, broadly speaking, the left auricle is formed from the left primitive vessel and the right from the corresponding right vessel; but as painful morbid conditions affecting the auricles alone are unknown the only use we can make of this fact here is the demonstration how the right and left position of the original elements in the auriculo-ventricular canal is preserved and may be traced.

The alimentary tract from pharynx to rectum has origin as a straight tube in the middle line bilaterally innervated. The œsophagus should therefore have its pains referred bilaterally near the middle line. The pains of stenosis of all kinds and of ulcerations are felt in the situation indicated, both sides of the viscus being usually affected; the higher the lesion the higher is the pain located in a line from the neck to the lower end of the corpus sterni. The swallowing of hot food or of a large or angular bolus is an everyday experience and the pain arising from it is felt to travel downwards, being especially acute at the lowest portion of the region mentioned which I believe corresponds with the cardiac sphincter of the stomach. I emphasise the point that these pains though median are bilaterally so in view of some conclusions to which the hypothesis has led with regard to unilateral median pains and hyperæsthesias in ulceration of the stomach.

James Mackenzie has shown that for morbid states in the stomach and small intestine the resultant hyperæsthesias are located near the midline, and especially has he demonstrated that the higher in the abdomen the hyperæsthesia the higher in the alimentary canal is the causative lesion. For instance, in a case of gastric ulcer in which the hyperæsthesia is located in the upper part of the epigastrium he finds the lesion at the cardiac end of the stomach, making his incision well to the left of the middle line; with hyperæsthesia low down in the epigastrium he searches with success the pyloric or duodenal region. From a consideration of the segmental condition of the fœtus in the vermis stage of development this seems quite what might be expected.

Now in cases of gastric ulcer resultant hyperæsthesia is often wonderfully circumscribed, as, indeed, is the lesion; a five-shilling piece or even a half-crown will cover the hyperæsthetic area at some stage in the history of the disease. Embryologically the anterior wall of the stomach is a left-sided structure and it is supplied by nerves from the left portion of the cord; by hypothesis, therefore, ulcers on the anterior wall should give rise to hyperæsthesias to the left of the midline. The commonest situation of a gastric ulcer is the lesser curvature where right and left nerves meet; this should give rise to hyperæsthesia bilaterally median. The proportion of ulcers on the left (or anterior) wall to those on the right (or posterior) is 69 to 235, and on the lesser curvature to the greater 288 to 27 (numbers taken from 793 cases collected by Welch and quoted by Osler). Of those ulcers situated on the lesser curvature it is no fanciful supposition, considering the numbers given, that there would be a preponderance of the right embryonic element in the lesion. So, taking gastric ulcer as a whole, one would expect from the hypothesis that the maximum hyperæsthesia and pain would be just to the right of the median line. The hypothesis suggests that a marked left median hyperæsthesia or seat of maximum pain is a localising symptom of lesion in the anterior wall of the stomach and that marked right median pain would point to a lesion on the posterior wall; and that were the median third of the epigastric region divided into nine equal areas the seat of an ulcer might in many cases be accurately located before operation, thus—*hyperæsthesia in upper right area, lesion cardiac and posterior; hyperæsthesia in lower left area, lesion pyloric and anterior, &c.*

Gastralgias without lesion have a situation in the epigastric area as vague as is their pathology and the hyperæsthesias and pains of cancer and chronic gastritis as diffuse as is their causative lesion, though a marked right or left hyperæsthesia or pain should by hypothesis locate the lesion on the posterior or anterior wall respectively.

To trace embryologically the hyperæsthesias and pains arising from the viscera will prove impossible without considering *those arising from affection of the peritoneum.* What has been said of the hyperæsthesias referred from gastric lesion applies to cases without peritonitis as a complication, a condition often existing in cases of gastric ulcer. The peritoneum, parietal and visceral, arises with the same left- and right-sided symmetry and innervation as does the gut. It will at once be seen that embryologically speaking the posterior wall of the stomach is in contact with right peritoneum, visceral and parietal—the lesser omental sac wall; and the anterior wall of the stomach is in contact with left peritoneum, visceral and parietal. Even extensive peritonitis therefore in stomach lesions will not affect the embryological orientation of the hyperæsthesia, though this will be spread laterally in area somewhat. In this connexion I may mention a case, of which I have lately heard, of peritonitis in the lesser omental sac from perforated ulcer on the posterior wall of the stomach; as by hypothesis it should be the hyperæsthesia was noticeably right-sided, though in the course of development the lesser omental sac is thrown to the left of the median line.

What has been said of stomach ulceration applies to duodenal ulceration, though here in a small viscus right and left sides are not so easily distinguished and even a small lesion is liable to invade both sides of the tube and give rise to bilaterally median pain. The posterior wall is right embryonically. As a matter of fact, duodenal ulceration is usually on the posterior wall and the referred pain to the right of the median line; this is as it should be by our hypothesis.

Lesions of the small intestine or temporary abnormal conditions of this part of the bowel usually affect its whole circumference. [illegible] should therefore be [illegible] Mackenzie gi[illegible] tion of intestine pains those arising from dietetic error. The descent in level of the pain in the abdominal wall is felt *pari passu* with the descent of the offending matter. With pain in the epigastrium relief by vomiting is possible, with pain in the umbilical area the hopeless feeling of "having to go through with it" is experienced; when the pain descends in the hypogastrium rejection per anum becomes a recognised possibility and eventually imperative. The pain throughout the attack is bilateral about the median line, though in intenser paroxysms, as is the case with all these gut pains, the pain extends into lateral regions and vertically. Meckel's diverticulum gives us an embryonic point which should correlate the small intestine save the last 43 inches with abdominal parietes above the umbilicus. The small intestine in its latter three feet and over is developed below the communication of the primitive gut with the yelk sac and its corresponding parietes will be situated below the umbilicus. On embryological grounds therefore we should look for any hyperæsthesia due to typhoid ulceration in a bilateral region below the umbilicus. I have demonstrated clinically that in the second and third week of typhoid fever in some cases there is a bilateral region of hyperæsthesia well localised in the lower half of the umbilical region. The large bowel would seem to take an inordinate share of the parietes for the manifestation of its grievances as compared with the small—nearly the whole of the skin and musculature about the midline below the umbilicus; but, as marked off by the outgrowth of the cæcum in the early fœtus, it will be seen to have nearly equal importance as to length with the future small intestine.

The intenser pains arising in connexion with these structures median in origin radiate into lateral regions, as also they do with less intensity in a vertical direction. Now if the lateral skin regions corresponding embryologically with the large intestines are those which cover the legs and the corresponding muscles are leg muscles, embryology would lead us to suppose that just as the abdominal muscles are thrown into tonic spasm and the abdominal skin in lateral as well as median regions rendered hyperæsthetic at the height of small intestine colic, so their homologues of lumbar and sacral innervation, the muscles and skin of the legs would be affected by radiation in intense colic of the large intestine. These pains in the legs—cramps—are often associated with abdominal pains and diarrhœa. I have lately carefully observed a case in which aching pain arising from internal piles—structures in themselves painless unless they have invaded the junction of proctodeum and hind-gut—was felt in the cutaneous distribution of the second, third, and fourth sacral nerves bilaterally.

Grave interest attaches to the embryology of the diverticula of fore and hind gut, in that it affords an explanation of the site of their pains and separates these pains from those due to complications in a way that cannot fail to have practical bearing. Surveying the embryology of the diverticula as a whole the trachea is a median diverticulum; since it quickly develops a right and left bronchus with their right and left innervation I need not insist on the right- and left-sidedness of this median tube. The common bile-duct arises from the fore gut anteriorly as if drawn out in continuity with a right and a left bile-duct around which the liver originates; this stamps the median bilateral nature of this duct. The typhlon is unpaired throughout, from its first appearance to its adult vestigial state, as is also the pancreatic duct, but the latter originates from exactly the opposite face of the gut to the bile-duct. I read the origin of these ducts in the light of the also unpaired cavity of the allantois which gives rise to the obviously median and bilateral bladder and in the light of that apparently cardinal law of origin of organs which applies alike to the begonia leaf and to the human liver—bilateral symmetry. Whether the cystic duct and the gall-bladder—diverticula of a diverticulum—are also median and bilateral in origin, embryology does not say, but on the basis already used I incline to the belief that these are indeed median and bilateral in origin.

A complication of the simple state of the origins of the bile and pancreatic ducts occurs in their further development in that these eventually open by a common aperture into the intestine, though originally on opposite faces of that tube. Taking the typhlon first in its pathological states the usual incitement to colic in the gut acts on this piece of developmental and structural gut, giving rise to pain and tenderness of a nature that should, and does, appeal to the laity as "stomach ache" and that in a site in the parietes depending on the origin of the typhlon. We have seen that the typhlon is median and bilateral in origin and it is developed below the site of Meckel's diverticulum where such exists. Therefore by hypothesis its pains and hyperæsthesias should be bilateral about the midline and situated below the umbilicus.

A colic arising in the umbilical area below the umbilicus of the nature of "stomach ache" is precisely the clinical phase of an attack of appendicular colic; if the conditions which lead to such an attack, which are just those which cause inflammation of the appendix, do not produce this latter result the phenomena are liable to lead to misdiagnosis and to the summary dismissal of the case to that group of uninteresting etiology yclept "stomach aches." In my own short experience I have met with two such cases where repetition of the attack and subsequent inflammation of the appendix and spread of inflammation to the peritoneum gave the clue to that diagnosis which I in similar cases now hold in view from the first. This pain of appendicular colic is rarely absent in cases of appendicitis. The cases without colic are dangerous, as perityphlitis is apt to occur without the danger signal of bilaterally median pain below the umbilicus, though if sought for I think a bilateral hyperæsthetic area would be found in this situation. The reason for right-sided pain and hyperæsthesia arising in connexion with appendicitis lies in the shifting of the peritoneal attachment of the cæcum and appendix with that of the ascending colon to the right, bringing the appendix into close relation with structures of right-sided origin and innervation, to wit, the peritoneum and subjacent tissues of that side; for appendicitis so-called is not appendicitis only nor chiefly. Treves, in his "System of Surgery," significantly speaks of perityphlitis, leaving appendicitis proper out of consideration as merged clinically in its own effects. However, in most first attacks, at the onset of each recurrent attack, and in some slight cases throughout bilateral median pain due to the appendix proper is the rule and is entirely in accord with the embryology of the viscus in which the attack originates. C. W. Mansell Moullin considers the initial pain of appendicitis to be due to the peristalsis of the appendix dragging on its mesenteric attachment.

Mackenzie cites a case of resection of bowel for umbilical hernia, without general anæsthesia, in which the upper end of the severed bowel contracted more than once whilst lying on a hot cloth; at each contraction the pain of colic was felt by the patient who referred this pain to the parietes. The circumstance would seem to preclude traction on the mesenteric attachment. It is true that the gut wall has no sensory nerves, but it is far less hypothetical to suppose that afferent nerves (not sensory), which it certainly does possess, give rise to referred pain, than to attempt to ascribe the pains of contracting gut throughout the length of the intestine to traction on the mesenteric attachment to the body wall. Mansell Moullin says[4]: "I have known even the slight pull caused by placing a ligature around a protruding portion of the colon bring on an attack of colic"—this as an instance of pain caused by a drag on the mesenteric attachment. It is my opinion that the ligature produced a spasmodic contraction of the bowel which gave rise to its own referred pain. It is beside the subject to query the same writer's view of the significance of McBurney's point and of a similar point posterior in situation.

Morbid states of the common bile-duct, since the duct is median and bilateral in origin and developed above the seat of Meckel's diverticulum, may be expected to give rise to bilaterally median pains and hyperæsthesia above the umbilicus. In cases of gall-stone colic we have an analogy with cases of appendicular colic, and the median pain in the upper region of the umbilical area is never wanting, but gall-stone colic being generally an incident in a long-standing cholelithiasis, which in its turn may be but the result of morbid states of the hepatic apparatus, often gives rise not only to its own pain but to right sided pains to which further reference will be made. I have myself met with two marked cases of gall-stone colic in which because of entire absence of right-sided pain gastritis was diagnosed, and the diagnosis was changed only by the course of subsequent attacks. A recognition of the fact that the common and cystic ducts are median in origin and bilaterally innervated, and should in accordance with the hypothesis give rise to pain bilaterally about the median line above the umbilicus, will concentrate the attention of the clinician in such cases on the exact area of the pain and of its maximum intensity and through this on that piece of gut which is the true offender.

The explanation of the right lateral pains coupled with gall-stone colic recorded in the greater part of the older literature of the subject, especially in text-books, and inextricably confused with the median bilateral pain, is that those are effects of complications, effects of morbid states induced in structures largely right-sided in origin either prior to the first attack of colic or often as a result of the first attack. After one or two attacks of obstruction and resultant inflammation have set up peritonitis about the duct, or in active cholecystitis or cholangitis at the time of an attack, pain would be referred to right regions of the body wall supplied by nerves from centres irritated by splanchnic afferent impulses passing from right lateral areas of peritoneum and subjacent tissue.

By hypothesis the pains and hyperæsthesias arising from the pancreatic duct should be bilaterally median above the umbilicus and in the umbilical area. This is not at variance with clinical experience. The hyperæsthesia of tracheitis, commonly known as "rawness in the chest," bilateral about the midline from the larynx to the level of third rib cartilages, is a matter of common experience. The pains arising from the bladder affections are mostly connected either with active spasmodic contraction or with passive resistance to over-distension; both sides of the bladder are generally concerned and its pains are bilaterally median as they should be in accordance with the bilaterally median origin of the allantois. It has more than once been hinted *that where peritoneum is involved in a morbid state of a* viscus referred hyperæsthesia is located in the right or left situation corresponding to the origin of that part of the peritoneum. This statement is not affected by the controversial point as to the direct sensibility of parietal peritoneum.

---

[4] THE LANCET, August 22nd, 1903, p. 514.

Of structures unilateral in origin I have little to say in support of my hypothesis: the clinical evidence is too clear to need discussion. The referred pain of ureteral colic is markedly lateral; that of the testis on which pressure is exerted no less so in the groin of its own side. The only viscus lateral and bilateral in origin and symmetrically developed, for discussion, is that resulting from the fusion of those originally lateral structures, the *Müllerian ducts*.

The pains of labour referred from the contracting uterus to the abdomen and back are well known. I will only draw attention to the fact that they are bilateral in order to emphasise that though bilateral they are not bilaterally median, as are the pains due to structures which I have designated median in origin. The halves of the uterus give rise to lateral pains, which, indeed, may fuse in the midline; the halves of the intestine give rise to pains about the midline which in their intensity may radiate into lateral regions. As to the pains and muscular contractions in the legs which so frequently appear in the course of labour these, which are homologous with the cramps of the legs in severe colic of the large intestine, are reflex pains set up in structures of the same segmental innervation as that of the Müllerian ducts. It seems inconceivable that so clumsy and dangerous a condition of affairs would have been perpetuated evolutionally were pressure on nerve roots in the pelvis the cause of these common cramps.

It is within the scope of this essay to speculate on those *comparatively infrequent cases where the* pain of stone in the pelvis of the kidney on the one side is felt on the opposite side and why, as I have observed, a patient may be operated on for appendicitis when only a ruptured left Fallopian tube is found to account for the pain felt on the right side. Is the pain felt in these cases really due to the lesion found? I would suggest that in such cases were fuller search made some structure in close relation in origin and development with the fellow to that in which the lesion exists may itself be found to be in a morbid state, giving rise to no pain but throwing the cord of its own side into an irritated condition by constant afferent impulses, a condition which if interfered with by an impulse transferred across the cord might readily give rise to pain. So correlated in origin and innervation are ureters, testicles, ovaries, spermatic cords, and Fallopian tubes. For instance, the right Fallopian tube being in a morbid state and a stone irritating the pelvis of the left kidney sufficient impulse might be transferred across the cord to explode a right sided irritability due to the Fallopian tube to the overshadowing of the pain due to the *stone on its own side*.

As my thesis has developed itself two points of interest have come into view. The one is that, leaving out cases in which peritoneum has been involved in the lesion and has complicated the pains, the pains due to structures referred to as median are distributed in the regions of the anterior cutaneous nerves in their maximum intensity and are often confined to those regions, while originally lateral structures give rise to referred pain in lateral cutaneous branches of the segmental nerves or their homologues. The same median and lateral distribution of referred pain when felt in the dorsal regions is observed. Viscera originating in the lateral mass have their afferent nerve fibres in close relation in the cord with those of lateral cutaneous branches; while median structures developed beneath the splanchnopleure have their afferent fibres correlated more closely in the central nervous web with anterior fibres of the segmental nerves. As to the significance of this I can only put forward the protective theory of the origin of pain as suggested by James Mackenzie, but if the protective theory of the origin of pain be correct it were obviously better had viscera median in origin preserved their state of the vermis stage of development median and unconvoluted and that lateral organs had never changed their position relatively to the body wall.

The parietal peritoneum with its uncomplicated orientation, be it sensitive or insensitive to direct stimulation, is only a partial corrective to the disturbance that has taken place between the relations of the visceral seat of lesion and the seat of resultant sensation in the body wall since the vermis stage of evolution. As I have shown in dealing with the medley of pains referred to the umbilical region, in that *specially protective sense of leading to a rapid diagnosis* the peritoneum often gives its lead all too late in the disease.

The other point is that, as regards pains, I have perforce dealt throughout with structures into the composition of which unstriped muscle tissue largely enters and that pain as opposed to hyperæsthesia is generally noticeable when that tissue is carrying out its function strenuously, either whilst in an abnormal condition or with an unusual incentive. The connexion between the working of the muscle and the production of the pain is very obvious in cases where such a cause as a pull on a mesenteric attachment is out of the question; it is on the ground of the generality of this element of muscular stress or strain in visceral pain that I *reject as unnecessary* a *cause referred to one viscus* which will not apply to an[illegible] I [illegible] that the origins of [illegible] inherent in the nerv[illegible] stress or strain.

To conclude on the main subject matter. My postulate on the preservation by viscera of their embryonic nervous connexions is far from unreasonable or indefensible and my hypothesis, save where it offers suggestions to the clinician, is amply borne out by clinical facts. There appears to be a good case, when searching for hyperæsthesia, when questioning as to pain and when drawing conclusions, etiological or diagnostic, from the sensory phenomena of morbid visceral states, for the utility of taking hints from embryology on the lines laid down.

Gravesend.

ON SO-CALLED INTRA-UTERINE CRETINISM AND ITS SUPPOSED IDENTITY WITH ENDEMIC AND SPORADIC CRETINISM.

BY DR. MED. H. BAYON,
ASSISTANT PHYSICIAN AT THE CLINIQUE FOR MENTAL DISEASES, WÜRZBURG.

THE object of my present communication is to show that up to the present time there is no conclusive proof for the occurrence of intra-uterine cretinism and that the cases which on different occasions have been published under this title[1] are to be reckoned as appertaining to the fœtal bone disease generally known as chondrodystrophia fœtalis or so called congenital rickets. I base my conclusions on microscopical sections of the bones of cases of chondrodystrophia fœtalis and cretinism which are to be found in the museums of the Pathological Institute and Clinique for Mental Diseases here, as also on slides which were kindly supplied to me through Professor Langhans of Berne (Switzerland) and on the results of the experiments of Hofmeister.[2]

Dr. J. W. Ballantyne had occasion at the seventieth annual meeting of the British Medical Association to point to the bewildering confusion which is caused by a too numerous nomenclature in fœtal bone diseases, especially where most of the terms employed are simply synonymous. What, since the appearance of Kaufmann's monograph in 1892, now generally carries the name of chondrodystrophia fœtalis has been called or described as achondroplasia, chondromalacic micromelia, fœtal rickets, so-called fœtal rickets, intra-uterine rickets, micromelic rickets, annular rickets, chondritis fœtalis, pseudo-chondritis, osteogenesis imperfecta, congenital or intra-uterine cretinism, cretinoid dysplasia, osteoporosis, osteopsathyrosis, periosteal dysplasia with osteopsathyrosis, and defective enchondral ossification. Ballantyne has adopted the nomenclature which Kaufmann made use of and makes accordingly a distinction between the following subdivisions of chondrodystrophia fœtalis—viz.: (1) hyperplastica; (2) hypoplastica; and (3) chondromalacica. The typical appearances of these three different diseases have been sufficiently clearly given by Kaufmann and Ballantyne.[3] I will therefore without delay settle the question which I have undertaken to explain.

---

[1] THE LANCET, Feb. 9th, 1884, p. 252; Brit. Med. Jour., Sept. 12th, 1896, p. 620; Barlow, Transactions of the Pathological Society of London, 1881.

[2] Beiträge zur Klinischen Chirurgie, 1894, Band xi., S. 441.

Since Virchow first described a specimen of chondrodystrophia fœtalis hypoplastica and came to the conclusion that it was a "new-born cretin,"[4] there has been the utmost difficulty in separating this disease from cretinism, especially as nobody dared to question Virchow's authority on the subject—in fact, the greater part of the following cases were described as "cretinism" and some authors went even so far as to refuse to acknowledge undoubted cretins as such when they did not present the features of Virchow's famous "neugeborne cretin." Having had by lucky chance the very identical specimen of Virchow in my possession I proceeded to make slides of the epiphyses and found on examination, as I expected, at the junction with the diaphysis a layer of connective tissue continuous with the periosteum. This was sufficient to stamp the case as chondrodystrophia fœtalis hypoplastica. In the bones of cretins one never finds such a fibrous cap over the end of the diaphysis; the bones of cretins have only this peculiarity—viz., that their ossification takes place exceedingly slowly, exactly as with infantile myxœdema and infantile dwarfs—i.e., dwarfs whose puberty is greatly retarded. In one of my previous papers I was able to give the radiographs of the hand of a patient, aged 12 years, suffering from infantile myxœdema in whom the ossification corresponded to the conditions of a child scarcely three years of age. In the museum of the clinique here there is the skeleton of a cretin who was 32 years old and whose pelvis is separable into the three parts (pars sacralis, iliaca, et pubica) which begin to be united at the age of six years. Even microscopically there is no great difference to be found between the bones of children whose real age corresponds to the apparent age of the cretins. The identity, from an etiological point of view, of sporadic and endemic cretinism and myxœdema has long ago been settled through Semon and Kocher, and if this fact has not had the unanimous agreement of all authors it is simply owing to the opinion that the small stature of endemic cretins was due to their cartilages becoming too soon ossified. The x rays have now shown the contrary to be the case, so that nowadays no serious objection can be brought forward to shake Semon and Kocher's theory. Cretins, sporadic and endemic, are nothing more or less than undeveloped children with the typical puffiness and intense apathy of myxœdema. On the other hand, cases of chondrodystrophia fœtalis, if they happen to grow up, which, though rarely, does sometimes occur, are as regards mental faculties perfectly normal and on a par with their surroundings and differ from other people only in this—viz., that their legs and arms are very short and stunted.[5] This shortness is simply caused through the above-mentioned strip of fibrous matter pushing itself between the diaphysis and the epiphysis and thereby putting a stop to further growth of the bone shafts. These points would be already sufficient to make a relation between cretinism and chondrodystrophia improbable. To this must be added that though up to the present time one has always found unquestionable pathologic changes in the thyroid gland of all cases of cretinism which have been carefully anatomically examined, this has never been so in the case of chondrodystrophia fœtalis.

I must now mention the experiments of Hofmeister, as they have often enough aroused the opinion that chondrodystrophia and cretinism bear some relation to each other. Hofmeister performed thyroidectomy on several rabbits of various ages and found that in the diaphysis of the operated animals the cartilage cells, instead of being arrayed in regular rows as usual, were apparently thrown about in the field of view. As this is also to be seen in chondrodystrophia fœtalis he came to the conclusion that this disease after all was only one dependent on loss of function of thyroid gland—i.e., cretinism. To this point the following objection must be raised, that the typical layer of connective tissue, continuous with the periosteum, never appeared at the junction of the diaphysis and epiphysis in any of the animals upon which he experimented, and that, moreover, a certain degree of "désarroi" does appear in the rows of the cartilage cells in all diseases of the bones without being typical for any one of them.

In conclusion, from all we know up to the present time of the function of the thyroid gland we must deduce that its loss brings on (1) general arrested development and (2) myxœdema. Both of these symptoms are wanting in chondrodystrophia fœtalis, in which disease we find simply short arms and legs, probably following inflammation of the cartilages during intra-uterine life. None of this is to be found in cretinism, therefore the two diseases are distinct units.[6]

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PNEUMOTHORAX WITH RAPID RECOVERY.

BY EDWARD FRANCIS COGHLAN, M.R.C.S. ENG.,
L.R.C.P. LOND.,
RESIDENT MEDICAL OFFICER TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

THE following case, owing to the unusual course it ran, seems to me to be worthy of record.

The patient, who was a man, aged 38 years, was admitted to the City of London Hospital for Diseases of the Chest on Oct. 21st, 1903, suffering from difficulty in breathing. The history he gave was as follows. He had been attending as an out-patient at the hospital since 1897 for cough, expectoration, and occasional hæmoptysis, but with the exception of one interval during which he had been an in-patient at the hospital he had been able to follow his occupation as a clerk. Until some ten days before admission he had been in his usual health, but about that time the cough returned and there was also a little blood-stained expectoration. On Oct. 17th, after a violent fit of coughing, he noticed himself becoming short of breath and about the same time he felt a "tapping sensation" behind the sternum and also heard a noise inside his chest on the left side which he compared to the sound of a pot boiling. On the 18th he felt the dyspnœa becoming worse and on the 19th it was so bad that he could not go to his work, although he attempted to walk there. He then sent for a medical man who advised him to seek treatment at the hospital.

At the time of admission his general strength was fairly good and, though he complained of dyspnœa and could not lie on his left side, he was not suffering from much distress. On examination of his chest some impairment of movement was observed on both sides, but while the right side showed some power of expansion, on the left side there was merely an elevation of the thoracic wall when he breathed deeply, no definite expansion being present. On palpation of the left chest behind vocal fremitus could be made out from the apex to the base over an area of three or four fingers' breadth parallel to the spine; over this area the percussion note was found to be impaired, the breath sounds were somewhat harsh, and vocal resonance was present. On palpating and auscultating over the remainder of the left chest it was found that vocal fremitus, vocal resonance, and breath sounds rapidly diminished and were soon lost as the examination was made at a short and then at a moderate distance from the areas of diminished resonance, but on percussion over this portion of the left chest the note was hyper-resonant. On examination of the heart the apex beat was not palpable; no area of cardiac dulness could be mapped out (being replaced by a hyper-resonant note) and the heart sounds were very faintly audible to the right of the sternum. On the right side there were signs of consolidation of the apex in front and doubtful cavity signs behind. The interpretation of the physical signs on the left side was as follows. The presence of breath sounds, of vocal resonance, and of fremitus in the dull areas mentioned above showed the presence of lung in those areas; their absence over the hyper-resonant area suggested the absence of lung in that area. In other words the left lung was in a state

[5] It will interest the readers of Dickens's works to be informed that Miss Mowcher in "David Copperfield" is a typical case of adult chondrodystrophia hypoplastica.

[6] I also believe that the "Cretinism in Calves," which Seligmann describes in the Journal of Physiology, 1903, vol. xxix., is only chondrodystrophia fœtalis after all.

air to cause a cavity; there

ve reached the pleura from without, consequently it must have done so from within. There was nothing to suggest that an air-containing viscus in the abdomen had opened into the pleura but there was evidence of lung disease, so it seemed that the free air had escaped from the lung into the pleura and so caused the collapse of the lung—in other words, the case was one of pneumothorax. An x-ray examination made by Dr. Hugh Walsham showed the left lung to be collapsed against the spine and also showed transmitted pulsation, and a transparent area corresponding to the air free in the pleural cavity could be made out. Dr. Walsham also took an x-ray photograph which showed (1) the displacement of the heart and mediastinum to the right side and (2) the line of collapsed lung and the transparent area extending from the apex to one of the lower ribs. The diagnosis of pneumothorax was therefore confirmed.

The patient was kept in bed and his symptoms rapidly changed for the better, so that he was able to leave the hospital much improved after a stay of six weeks. A week after admission another x ray photograph was taken[1] and it showed *a return of the heart to almost, but not quite* (as could be demonstrated by percussion), its normal position; it also showed the re-expanded lung with tuberculous infiltration and a small cavity at the extreme apex. The breath sounds, the vocal resonance, and the vocal fremitus could also be made out all over the left thorax, proving therefore that the lung had expanded. In addition to the above it was noted that in the upper quarter front and back the vocal resonance and the vocal fremitus were more marked than normal and there was prolongation of expiration with some medium sized râles showing that this part was already infected. On the right side there was not any change of importance to note.

The following points in the case are worthy of special attention.

1. It is interesting to note the comparatively small amount of distress that the patient had. This might be explained in two ways: either the opening in the pleura was valvular and allowed small quantities only of air to escape at a time or else the pneumothorax was only an incomplete one.

2. *It is also interesting to note the* extreme rapidity of recovery, the patient's mediastinum having regained nearly its normal position at the end of the week. This observation was verified by Dr. Harrington Sainsbury and Dr. Walsham.

3. Another point of interest is that there was no evidence of fluid, for there was never any splashing nor could any fluid be made out by means of the x rays.

4. The case illustrates how important it is in the diagnosis of chest disease to recognise the dislocation of the various thoracic viscera. The diagnosis in this instance largely rested on that fact. The bell sound was entirely absent throughout the case.

I have to thank Dr. Sainsbury for permission to publish the case and also Dr. Walsham for the x-ray photographs.

A CASE OF FRACTURE OF THE SKULL BY CONTRE-COUP; RECOVERY.

BY ANGUS E. KENNEDY, M.R.C.S. ENG., L.R.C.P. LOND.

GENUINE fracture by contre coup is rare and recovery after it is so rare that the following case seems worth putting on record.

In the early part of 1903 a boy, aged 12 years, at Cleggan in Co. Galway was kicked by a horse over the right coronal suture; a compound depressed fracture resulted and the orbital plate of his right frontal bone was torn from the orbital margin and its sharp edge could be felt below the upper eyelid under the protruding conjunctiva. Two months after the accident he was brought to London by the kindness of Sister Katherine and I saw him. His cerebral functions were at that time perfect so far as could be discovered. On the vertex there was a depression with a stellate scar. His upper right eyelid bulged and pulsation could be seen through it. Below the lid the protruding conjunctiva could be seen and the sharp orbital plate could be felt under it and could be moved up and down. The globe lay over the lower lid disorganised but intact and was almost hidden by the conjunctiva. I carefully excised the globe and the protruding conjunctiva, but did not expose the actual edge of the orbital plate, as I saw no way of fixing it or of preventing subsequent hernia cerebri.

The result is very good; the upper lid has sunk back and the pulsation is no longer visible through it though it can be felt; the brain seems to occupy the whole orbit and the appearance is like that of a boy with exaggerated ptosis.

Plaistow, E.

A NOTE ON THE TREATMENT OF SCIATICA.

BY ARTHUR H. BOSTOCK, L.R.C.P. LOND., M.R.C.S. ENG.

WHILE house physician at St. Bartholomew's Hospital I was much struck with the number of cases of sciatica which were not amenable to ordinary methods of treatment and the object of this note is to recommend the use of a remedy to which I have now given a thorough trial. It *has been of most use in the cases of true neuralgia, which in* my experience are the commonest, but it has not acted quite so well in the cases associated with a rheumatic diathesis. The dru

House,

five to 20 grains and I find that this substance so given has no depressing action on the heart, neither does it expose the patients to the risks incurred in the use of such analgesics as opium and morphia. When a case is in the acute stage the patient should be placed in the recumbent position and poultices should be applied locally. A commencement should be made with phenalgin in a dose of ten grains, repeated every three hours. After the first 24 hours, if the drug is acting, I reduce it to ten grains (four tablets) three times a day and next day to three tablets (seven and a half grains) three times a day. I then leave a few tablets with the patient to take a dose of ten grains should the pain show a tendency to recur. In my experience doses consisting of less than three tablets (seven and a half grains) are of no use at all.

QUEEN'S HOSPITAL, BIRMINGHAM.

A CASE OF AN UNCOMMON FORM OF SPINA BIFIDA.

(Under the care of Mr. W. BILLINGTON.)

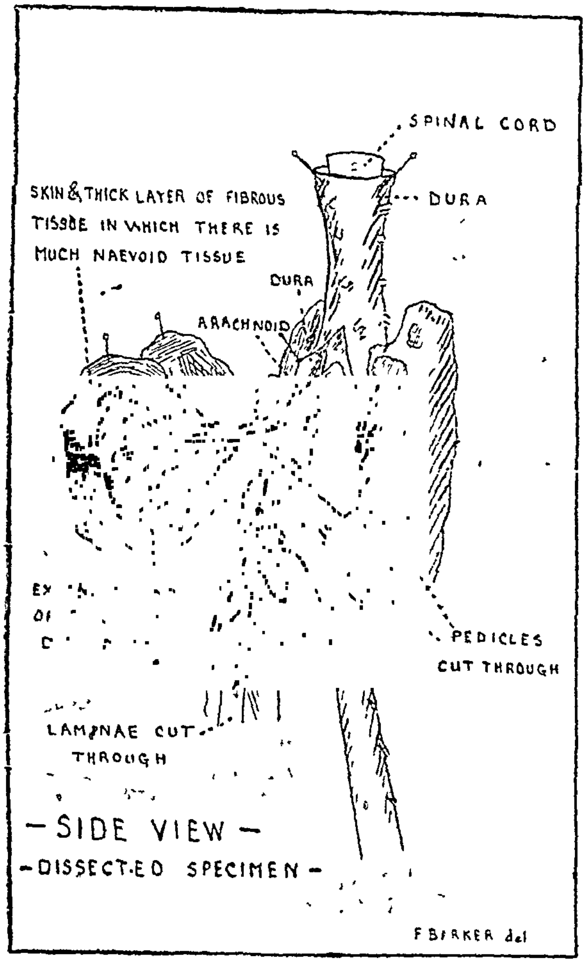
FOR the notes of the case we are indebted to Mr. Frederic Barker, house physician.

who has

under the care of Mr. Billington, for the purpose of having a small tumour removed from the upper dorsal region of the back in the middle line. The lump, almost sessile but narrowing slightly to form a short stalk, was regarded as a nævolipoma; it was covered with wrinkled skin and was soft and doughy, not fluctuating, and of about the size of a walnut. Within the stalk a cord could be felt running forwards between the first and second dorsal spines. No interval could be felt in the laminæ of the adjacent vertebræ. The condition seemed to be one of spina bifida occulta, in which peculiarities of the skin, such as moles, wrinklings, hairs, &c., are common. On the day following admission the temperature went up to 103° F. Operation was out of the question; the high temperature continued and there were physical signs of broncho-pneumonia, to which the patient succumbed four days after admission into hospital.

---

[1] The paper was accompanied by two admirable skiagrams which if reproduced would have occupied a considerable space. They quite corresponded with the description of them given by the author.—ED L.



The illustration represents a side view of the spinal cord and tumour with their connexions dissected out. It was found that the cord within the stalk consisted of a narrow offshoot from the dorsum of the cord, together with prolongations of the meningeal coverings. The central nerve element of the stalk was widest vertically near the cord; it sprang from the columns of Goll and lay over the postero-median groove. Emerging between the spines of the first and second dorsal vertebræ the dura mater widened out in the tumour to form a cystic structure with irregular translucent looking walls, on which the arachnoid and the central part of the stalk lost themselves. The superficial part of the tumour was one-quarter of an inch in thickness and was made up of skin and fibrous tissue in which there was also nævoid tissue. The laminæ of the first and second dorsal vertebræ were both somewhat deficient in osseous growth. The cartilaginous spine of the upper vertebra was large and both were slightly bifid towards the stalk, though there was no complete median hiatus. The narrow central slip from the cord has not been further dissected; probably it contains very little true nerve tissue. The arrangement of the posterior roots was not altered. The specimen was looked upon as a meningo myelocele, though, as Dr. Stanley Barnes (who performed the necropsy) suggested, imagining the narrow nerve stalk to contain a potential canal connecting the external cyst with the central canal of the spinal cord the condition must be regarded as a modified syringo-myelocele, itself an extremely rare phenomenon.

Remarks by Mr. BARKER.—It is interesting to compare the above with a case described by Mr. H. H. Clutton.[1] The sac in that case, which was clinically like a simple meningocele, was found to contain nerve tissue, dura mater, and arachnoid. Mr. S. G. Shattock, who reported on the post-mortem specimen, said that the protrusion consisted "not only of the spinal membranes, but of the cord extruded by a dilatation of the central canal." He termed it a meningo-myelocele. Comparison can also be made with Specimen 22 referred to by the Clinical Society's committee on Spina Bifida.[2] The present specimen, which is now in the Pathological Museum of the University of Birmingham, is uncommon also in its position. Out of 236 cases described by the Clinical Society's committee only 14 (or 5·9 per cent.) were noted in the dorsal part of the spine. Of the 125 pathological specimens only 7·2 per cent. were in this situation. Cases occurring in the dorsal, and especially the upper dorsal, spine are all the more interesting when we consider that the medullary folds of the embryo first join in this region. During life there were no symptoms or deformities which could be ascribed to the tumour or to its connexions. I am indebted to Mr. Billington for permission to publish these notes.

LEEDS GENERAL INFIRMARY.

A CASE IN WHICH A GALL-STONE WAS REMOVED FROM THE GALL BLADDER; SUBSEQUENT DEVELOPMENT OF MALIGNANT DISEASE OF THE GALL-BLADDER; DEATH FROM SUPPURATIVE CHOLANGITIS.

(Under the care of Mr. R. LAWFORD KNAGGS.)

A SPARE woman, aged 69 years, who looked, and expressed herself as being, very healthy, was admitted into the Leeds General Infirmary on Sept. 8th, 1902. She had never had any trouble with her digestion or her bowels except some slight diarrhœa two years previously. Seven weeks before admission she felt pain in the right hip which "let her down" when she walked. The pain gradually mounted higher till it was felt over the lower ribs and a medical man discovered a tumour in the right loin. She had never been jaundiced or had any attack of severe abdominal pain and she had lost no flesh. She had a goitre of long duration which caused no trouble. On examination a smooth, rounded swelling was found in the right lumbar region. It was evidently attached to the liver and was regarded as a distended gall-bladder which from its mobility was free from adhesions. A tender spot was always to be found on pressure at a point midway between the umbilicus and the tip of the ninth rib and a gall-stone impacted in the cystic duct was diagnosed. The urine was normal.

On Sept. 11th the patient was anæsthetised and an incision was made over the gall-bladder. This, much elongated and distended to the size of a fist, was drawn out of the wound and a quantity of foul-smelling fluid with some pus was evacuated by the aspirator. A single stone was felt in the cystic duct and was squeezed back into the gall-bladder and removed. It was of about the size of a nutmeg, oval and not faceted. The gall-bladder was very long and supple and not noticeably thickened. No suspicion of anything abnormal was raised by the examination of the cystic and common ducts which was made in the routine manner. An india-rubber tube to carry away the bile was now fixed in the gall-bladder which was then attached to the aponeurosis, but owing to its length its terminal portion was allowed to lie above the aponeurosis and between the lips of the incision through the soft parts. From this circumstance the fistulous opening failed to close in the ordinary way but the amount of bile that came from it steadily diminished and became so trivial that it proved to be no discomfort to the patient. Consequently no thought of doing anything to close it was entertained. The following report upon the fluid removed from the gall-bladder was made by Dr. J. A. C. Forsyth: "On agar there was an active growth in five hours. At the end of three days culture examined. Foul odour noticed on withdrawing plug from tube. Film preparations show bacillus coli communis in pure culture."

The patient left the hospital on Oct. 19th. She was seen from time to time as an out-patient and except for the fistulous opening discharging a very little bile she was quite well. About the end of 1903 she came complaining of pain in the right hypochondrium. She stated that the fistula had closed and that th [illegible] had ceased. Some [illegible] cicatrix of the fistula [illegible] to the redundant por [illegible] allowed to remain in [illegible] two or three weeks she continued to attend as an out-patient but the pain then became so continuous and so distressing that she was glad to consent to the fistula being re-established. During this time she lost flesh. She was re-admitted on Jan. 23rd, 1904. The urine was normal. On [illegible] was made [illegible] he mucous [illegible] e quantity of mucus with some purulent dregs escaped but no stone could be felt with a probe. The intense pain was relieved by the operation but the patient did not seem to recover her spirits. On Jan. 28th she had a rigor and the temperature rose to 105° F. She had another rigor on the 29th (the temperature being 102°) and on Feb. 4th the temperature rose to 103° and gradually fell but with these exceptions the temperature kept about the normal throughout. The pulse varied from 72 to 100 but it averaged from 80 to 90. Two or three days after the first rigor jaundice was first noticed and marked tenderness on pressure was present in the middle line above the umbilicus. The jaundice increased and was evidently due to obstruction. The left lobe of the liver enlarged and reached almost to the umbilicus and all over it was very tender. There was also much pain in the right hypochondrium and round the right lower ribs. The mucus coming from the gall-bladder became *bile-stained*. The patient complained of feeling very ill and was listless and often drowsy. Albumin appeared in the urine and there was œdema of the legs and abdominal wall. Gradually she passed into a semi-conscious state, petechial spots and vesicles appeared over the body, and she died on Feb. 17th.

[1] Transactions of the Clinical Society of London, vol. xix.

[2] Ibid., vol. xviii.

[illegible] er, examined the blood on [illegible] "Red cells, 4,800,000 per [illegible] 0,000 per cubic millimetre. The neutrophile leucocytes predominate. This result is quite in accordance with the blood fluid in cases of malignant disease."

Necropsy.—At the post-mortem examination the liver was somewhat enlarged. On laying open the gall-bladder through the fistulous opening it was found to be the seat of malignant disease. Its walls were infiltrated with growth to the thickness of nearly half an inch and the growth extended to, and involved, the cystic duct, practically occluding it. Neither the hepatic duct nor the common bile-duct was affected but the growth involving the cystic duct had pressed upon, and partially obstructed, the commencement of the common duct. Above this stricture the ducts were much dilated and were the seat of suppurative cholangitis. The surface of the liver showed numerous cystic elevations due to the dilated terminal ducts and on section the dilated bile-ducts were found to be filled with pus. A small secondary nodule of growth was present in the left lobe near its anterior margin. No gall-stones were found. The pancreas was normal. The kidneys were small and slightly granular. As regards the chest, there were some adhesions in both pleural cavities and both lungs were the seat of chronic bronchitis. The thyroid gland was the subject of fibro-cystic enlargement. The other organs were normal. Microscopic examination of the growth showed it to be a columnar carcinoma.

Remarks by Mr. Lawford Knaggs.—It cannot be certainly affirmed that the malignant disease had not commenced when the first operation was performed, but it was quite unrecognisable by the finger or by sight, and the presumption consequently is that it was of later origin. There were two sources of irritation present if the temporary use of a drainage-tube be disregarded: one, a gall-stone, which was removed presumably before the commencement of the growth, and the other the bacillus coli communis. It is probable that this latter source of irritation was never thoroughly eradicated from the gall-bladder or its glandular recesses, for when the fistula closed owing to the blocking of the cystic duct by the growth the mucus which collected soon became mixed with pus. Unfortunately no cultures were made from the gall-bladder contents at the second operation so that this point cannot be placed absolutely beyond doubt. The case, however, is of considerable interest from its bearing upon the etiology of carcinoma of the gall-bladder.

SEAMEN'S HOSPITAL, LAS PALMAS, CANARY ISLANDS.

A CASE OF ENTERECTOMY FOR GANGRENOUS HERNIA.

(Under the care of Dr. J. Cleasby Taylor and Dr. Rafael Gonzalez y Hernandez.)

The patient who was a Norwegian, aged 18 years, was a sailor on board a Norwegian steamer and was admitted into the Las Palmas Seamen's Hospital on Oct. 20th, 1903. He had been troubled with a right inguinal hernia for five years, though latterly it had shown no sign. On the morning of admission a swelling appeared in the scrotum, accompanied by pain and vomiting. On examination a right inguinal hernia was diagnosed. Attempts to return the mass having been already made and the parts having become very tender ice was applied and an enema was given, this latter producing two movements of the bowels. As there was no vomiting, distension, or abdominal pain it was decided to await symptoms and the subsidence of the inflammation. During the next four days the bowels were moved four times by means of enemata, the tongue remained clean, the pulse-rate was from 56 to 60, the abdomen was flaccid, and the tumour became less swollen and tender. On Oct. 24th, after Dr. Taylor had consulted with his friend Dr. Gonzalez, a hypodermic needle was introduced and some very foul dark brown fluid was drawn off. As it was thought that there might perhaps be a decomposing hæmatocele the tumour was immediately cut down upon under chloroform, and on opening the sac six inches of bowel were found in a gangrenous condition, the fluid extracted being contained in the lumen of the bowel. The gangrenous portion was removed and the divided ends were joined together by means of ten interrupted catgut sutures, these passing through the serous and muscular coats only. The clamps being taken off peristalsis was observed on both sides of the suture, with evident passage of contents and no leakage; the crural canal was then enlarged and the intestine was returned to the abdomen, the external wound being closed in the usual way. After the operation there was neither abdominal pain nor distension, the wound healed quickly, and the patient was out of bed in three weeks. On the fourth day, after an enema, the bowels acted for the first time and regularly thereafter. The patient's highest daily recorded temperatures were as follows: on Oct. 20th, 97·6° F.; on the 21st, 100°; on the 22nd, 100·4°; on the 23rd, 98·4°; on the 24th (the day of the operation), 98·4°; on the 25th, 101°; on the 26th, 100°; on the 27th, 99°; and on the 28th, 99·2°. After this date it did not rise above 98·4°.

Remarks by Dr. Taylor and Dr. Gonzalez.—There were three points of interest in connexion with this case. 1. Notwithstanding the gangrenous condition of the bowel there was for four days no symptom indicative either of strangulation or of septic absorption. On the contrary, the condition of the man in general and of the part in particular was better. If it had not been for the fluid withdrawn by the hypodermic needle we should probably instead of operating have awaited further symptoms. 2. The operation was done with the instruments we had sterilised for the incision of the swelling, without any buttons or proper clamp, the shank handles of Thornton's T forceps being used as clamps. 3. The rise in temperature on the day after the operation was undoubtedly due to septic absorption from the divided ends of the bowel. Five-grain doses of salol every three or four hours acted well.

Gloucestershire Infirmary and Eye Institution.—The annual meeting of the governors of this institution was held on March 31st under the presidency of Colonel Curtis Hayward. The medical report stated that 1235 in-patients were admitted during 1903, compared with 1335 in 1902. The out-patients numbered 7743, against 8473 in the previous year. The financial statement showed that the receipts amounted to £7558 and that the expenditure was £7839, leaving an unfavourable balance of £281. It was stated that of the £10,600 required for the nurses' home and other improvements the sum of £7518 has been already received.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Mental Condition in Epilepsy in Relation to Prognosis.—Peptic Ulcer of the Jejunum.—Carcinoma of the Rectum.

A meeting of this society was held on April 12th, Sir R. **Douglas Powell**, the President, being in the chair.

Dr. W. **Aldren Turner** read a paper on the Mental Condition in Epilepsy in Relation to Prognosis, a full report of which was published in The Lancet of April 9th, p. 982[1]—The **President** asked if Dr. Turner was able to define in any precise way the facies epileptica and also whether he had been able to observe any pathological change characteristic of epilepsy.—Dr. **Fletcher Beach** said that since an epileptic child was uneducated the mental deterioration was more marked than it would be in the adult. He had been able to note great improvement in those epileptic children who had been educated. It was a well-known observation that the mental impairment was often greater in cases of petit mal than in cases of major epilepsy.—Dr. C. **Hubert Bond** said that at the recently started County Council Colony for Epileptics at Epsom he had had under observation cases which differed only in degree from those seen by Dr. Turner. He said that it was important to note what other members of a family might be mentally affected and especially in how close a connexion they stood with the patient. He had noted that first-born children were frequently epileptic and this he attributed to the difficult labour of the primipara. He also thought that the youth of the parent was an important factor.—Dr. **Turner** replied.

Mr. A. W. **Mayo Robson** communicated a paper on Peptic Ulcer of the Jejunum and gave a list of all the reported cases, 15 in number, his being the first, so far as he could ascertain, recorded in English literature. All the recorded cases had occurred after gastro-enterostomy, nearly all of them being after the anterior operation, and in all perforation had occurred. He gave some statistics bearing on the frequency of peptic ulcers. Out of 128 posterior gastro-enterostomies that he had personally performed there had been no instance of jejunal ulceration. Out of 29 anterior gastro-enterostomies he had had the one case he was now reporting. After some remarks on the pathology he described the symptoms and treatment of the condition. He then related his own case which had occurred three years and four months after an anterior gastro-enterostomy performed for pyloric and duodenal ulcer, the patient having been in the interval well for two years. At the operation he had excised the ulcerated portion of the jejunum and then performed Roux's operation. The patient made a good recovery and was now well.—Mr. F. C. **Wallis** asked why a peptic ulcer should be commoner in an anterior gastro enterostomy than in a posterior? —Mr. D. J. **Armour** asked whether the stenosis of the pylorus referred to in the paper was due to simple cicatrisation or whether it became closed owing to loss of function.—Mr. H. J. **Paterson** asked whether the adhesions which were present were secondary to the perforation of the ulcer.—Mr. **Mayo Robson** said that he thought that peptic ulcer was more liable to follow anterior gastro enterostomy because it was less efficient in draining the stomach than a posterior gastro-enterostomy. The adhesions which formed were the result of perigastric inflammation and these often prevented peritonitis when perforation had occurred. He had frequently found adhesions round a perforated gastric ulcer. He thought the closure of the pylorus was due entirely to cicatrisation and not to loss of function.

Dr. H. J. **Cotton** reported a case of Ulceration of the Rectum. The patient, a man, aged 44 years, who had always had a sallow complexion and never had syphilis or gonorrhœa, first began to pass blood and mucus four years ago. Two years ago he was examined and an ulcerative stricture high up in the rectum was found and was diagnosed by a surgeon as carcinoma and colotomy was advised to relieve pain. The patient declined colotomy and attended his work daily with the help of cocaine and morphine suppositories. A year later Mr. W. Arbuthnot Lane suggested incising the stricture as the ulceration had diminished but shortly afterwards high fever, diarrhœa, and tendency to delirium set in, simulating typhoid fever. No implication of the neighbouring glands could be detected. This grave condition lasted six weeks and there was evident burrowing of pus and fæces in the tissues which finally came to a head in a large ischio-rectal abscess which Mr. Lane incised. On March 19th, 1903, the patient was admitted to Guy's Hospital in a desperate condition and Mr. Lane performed colotomy in the left iliac region, although the microscopical report of a piece of ulcerated rectum was "columnar-celled carcinoma." The operation was performed in four stages: on April 1st an incision was made and the colon was stitched to the skin but not divided. To allay the suffering from the consequent obstruction and distension morphine was given till the fifth day when the bowel was divided and Paul's tube was inserted. On the eighth day the protruding loop of colon was cut through and the lower end was clamped and Paul's tube removed and on the eleventh day the clamp was removed. The patient made a steady recovery and left the hospital in six weeks and was very soon able to resume his work. He had now regained his usual weight of 14 stones, though at the time of the acute illness he weighed about 12 stones. There was still occasional discharge of mucus and blood from the anus but he had lost the intolerable pain and found no discomfort from the artificial anus for which no belt or pad was worn. Dr. Cotton submitted the following questions: 1. What was the man's complaint? 2. Was not the fact that he recovered from the blood poisoning of burrowing pus and fæces sufficiently to allow of colotomy and had now enjoyed ten months' good health, regaining his natural weight of 14 stones, inconsistent with the theory of cancer of three years' standing? 3. Did not true cancer live upon its host and produce emaciation and a cachexia in which such a serious operation would have been fatal? 4. Was the microscope at fault?—or, rather, was the microscopist at fault?—for columnar cells were the natural cells of the epithelium of the intestine. 5. Was it wise to apply the term "cancer" to diseases of low malignancy which might last for years?—The **President** said that he had seen cases with a long period of quiescence after colotomy.—Mr. **Mayo Robson** said that if inflammation was added to carcinoma of the rectum there was a great accession of symptoms and if this inflammatory condition could be relieved a very marked improvement might take place. He referred to a case of five years' duration. The lesson to be learnt from this case was that a radical operation should be performed early if the growth was limited and if it had advanced too far for this a colotomy should be performed. He referred to several cases which appeared to be undoubted cases of carcinoma and in which after a colotomy had been performed the growth entirely disappeared.—Mr. **Paterson** referred to the value of a microscopical examination and said he had seen a patient who, three and a half years after colotomy for carcinoma, was in good health.—Mr. **Wallis** said he had examined Dr. Cotton's patient and he had no doubt that he had carcinoma of the rectum. He suggested that tubercle might sometimes simulate a carcinomatous mass.—Mr. **Armour** referred to a case of a long quiescent period after colotomy.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A meeting of this society was held on April 11th, Dr. F. **de Havilland Hall**, the President, being in the chair.

The **President** exhibited a case of Thoracic Aneurysm occurring in a man, aged 45 years, who was formerly in the army. In 1884 he had syphilis. He first noticed a pulsating swelling in the front of the chest two years ago. This was accompanied by slight pain in the region of the swelling and between the shoulder blades which extended down the front of the right arm, but the case was one of aortic aneurysm attended by physical signs rather than subjective symptoms. There were evidences of dilatation of the first part of the aorta associated with aortic incompetence. Tracheal tugging was well marked. The treatment of such cases was, in the President's experience, extremely unsatisfactory.

Mr. J. **Hutchinson**, jun., exhibited a case of Undescended Testis (complicating Hernia) brought down into the scrotum by means of section of all the structures of the cord except the vas deferens and its accompanying vessels.

---

[1] The premature publication of Dr. Aldren Turner's paper was due to an error which we much regret.

The patient was a man, aged about 25 years. He had an inguinal hernia on the right side and the corresponding testis had never descended outside the abdomen. On operation by slitting up the inguinal canal the testis was found to be of fair size and consistence but it could not by any traction be brought below the pubes after the fascial coverings had been divided by reason of the inextensibility and shortness of the spermatic vessels. These, the anterior bundle of veins and the artery, were divided between two ligatures, taking care to leave the vas deferens and its artery. During the two months that had elapsed the testis had become somewhat harder. The patient would have beennone the worse off if the testis had been excised and Mr. Hutchinson could not recommend this method of treatment. This operation was not altogether new and it could not be regarded as successful.

Dr. H. TILLEY exhibited a case of Frontal Sinus Empyema treated by Operation. The patient was a woman, aged 50 years, who had suffered from nasal discharge for some years due to nasal polypus and recurrent hoarseness which was due apparently to inter-arytenoid pachydermia (so called). It was a noteworthy fact that the latter had disappeared after the radical cure by operation of the frontal sinus empyema.—The case was discussed by Dr. G. WILLIAM HILL and the PRESIDENT.

Dr. TILLEY also showed a case of Asthma relieved by Intranasal Operation. The patient, a man, aged 22 years, had suffered for three years from attacks of spasmodic asthma for which the usual medicinal remedies had been tried with very little relief. For 18 months he had slept in an upright position, the air being impregnated with the fumes of "asthma powders." Examination revealed well-marked moriform hypertrophy of the mucous membrane covering the inferior turbinal bones. On Sept. 21st, 1903, these were removed and there had been complete relief from the asthma since the operation. Dr. Tilley had undertaken the operation with some misgiving as to the result but the relief had been very marked. In his experience such operations for the relief of asthma were more often successful when there were greater nasal lesions than in cases where the nasal lesions were slight, which was the converse of the view held by some observers.—Mr. R. LAKE remarked that he had met with many cases in which the removal of polypi failed to cure the associated asthmatic attacks —Dr. H. A. CALEY referred to the case of a highly sensitive girl in which operation relieved the asthmatic attacks but determined the occurrence of epileptiform attacks.—Dr. HILL believed that about 50 per cent. of polypus cases were relieved of their asthma and some were quite cured, as in Dr. Tilley's case.—The PRESIDENT remarked that if the symptoms of asthma had lasted for years there was not much prospect of relief by operations for nasal stenosis, but if recent they were amenable to such treatment.

Mr. LAKE exhibited a case of Ménière's Disease after operation (previously shown before the society in February, 1904) occurring in a woman, aged 21 years. The symptoms had been vertigo, deafness, and tinnitus. Hypodermic injections of pilocarpine and many other remedies had been tried without success. The patient had her semicircular canals on the left side removed on Feb. 15th, 1904, and since the operation she had not had any further symptoms of vertigo. The malleus and incus were also removed at the time of operation, yet the voice could now be heard at a considerably increased distance (five feet as compared with two inches). Mr. Lake was unable to explain this fact. The tinnitus had persisted.—Dr. HILL commented on the extreme importance of this case, especially in view of its obvious success. Fulminating vertigo was sometimes due to reflex causes and the indiscriminate handing over of such cases to the aural surgeon was to be deprecated.—Dr. TILLEY and the PRESIDENT commented on the advantages to be derived by attacking such cases by surgical measures; these patients often terminated their lives by suicide.

Dr. WILFRED HARRIS exhibited a case of Post-diphtheritic Chronic Bulbar Paralysis in a man, aged 25 years. In 1897 he had had scarlet fever, followed by desquamation, and six weeks after recovery he had a very sore throat and could not swallow without great pain for four or five weeks. Six weeks later he noticed [illegible] al regurgitation. He had [illegible] food since and had much d[illegible]. Since the commencement [illegible], though he could do so before. Four years ago he lost his voice completely for six weeks. He had been slightly worse during the last six months and had noticed slight diplopia twice in the last six weeks, but on the whole there had been practically no variation in the symptoms since the commencement six years ago.—Dr. SIDNEY P. PHILLIPS ventured to doubt the diphtheritic nature of the throat lesion; it might be scarlatinal or septic.

Dr. CALEY exhibited a case of Abdominal Cyst, probably of pancreatic origin, occurring in a man, aged 58 years, in whom the symptoms of diabetes had existed for about four months. The patient stated that for 15 years he had been "getting stout" but he had had no pain or other abdominal discomfort. At the present time there was marked distension with special bulging anteriorly, rather more on the right side than on the left. Dr. Caley dismissed the possibility of other abdominal cystic disease such as mesenteric cyst or a localised ascites.

OBSTETRICAL SOCIETY OF LONDON.

Puerperal Eclampsia treated by Thyroid Extract.—Fibromyoma of the Uterus with Carcinoma of the Body and Fibroid Tumour of the Ovary.—Adeno myoma of the Uterus.—Torsion of the Pedicle in Hydrosalpinx and other Morbid Conditions of the Fallopian Tube.

A MEETING of this society was held on April 6th, Dr. EDWARD MALINS, the President, being in the chair.

Lieutenant-Colonel A. J. STURMER, I.M S., read a short communication on 41 cases of Puerperal Eclampsia treated by Thyroid Extract. Ten grains of thyroid extract were given in each case on admission and five grains every four hours afterwards. Morphine and saline injections were also used in many of the cases. Rupture of the membranes, followed by dilatation of the cervix and the early application of forceps or other means of assisting labour, was the usual practice adopted. Under thyroid treatment the maternal mortality was reduced to 12·2 per cent. It was claimed that the urine after the first two or three doses showed considerable increase and that by the end of 24 hours the increase was great, whereas with saline injections and morphine alone no marked improvement usually set in for 24 hours. It was remarked that most of the cases of eclampsia occurred on dull and cloudy days, when probably the skin did not act as well as usually.—Dr. G. E. HERMAN considered that increase in the urinary excretion was one of the most trustworthy indications of recovery of the patient and that as when thyroid was given the quantity of urine became quickly augmented this preparation was really beneficial.—Dr. R. BOXALL said that he had recently learnt that eclampsia was unduly prevalent in the West Indies as well as in the East. This was attributed by the local medical men to malarial influence.—Dr. H OLIPHANT NICHOLSON considered the results of treatment of cases of eclampsia and of impending eclampsia by thyroid extract as very encouraging. In severe cases he always used morphine in addition.—The PRESIDENT remarked on the difficulty of determining the value of thyroid extract treatment from a series of cases of eclampsia in which other remedies were at the same time used. He was of opinion that atmospheric conditions often exerted a potent predisposing influence in the production of cases of eclampsia.

Dr. W W H. TATE, in exhibiting a specimen of Fibromyoma of the Uterus with Carcinoma of the Body and Fibroid Tumour of the Ovary, emphasised the importance of exploring the uterus in cases of hæmorrhage persisting for years at about the time of the menopause and later, because in these cases malignant disease of the body was a very probable cause of the symptoms.—Dr. A. H. N. LEWERS and Dr. BOXALL referred to similar cases of carcinoma associated with fibro myoma which had come under their observation.—Dr. P. HORROCKS called attention to the fact that bleeding from the uterus after the climacteric in a woman known to have a fibroid tumour did not necessarily indicate malignant disease of the uterus as in this case or malignant degeneration of the fibroid. Some authorities disputed the possibility of the latter but Mr. Alban Doran and he himself had shown specimens illustrating sarcomatous changes in fibroid tumours.

Dr. TATE also showed two specimens of Diffuse Adenomyoma of the Uterus.—After remarks from Dr. STEVENS, Mr. J. BLAND-SUTTON, and Dr. F. E. TAYLOR these specimens were, on the motion of Dr. G. F. BLACKER, referred to the pathology committee.—Dr. BLACKER remarked that they were the first examples of this kind of tumour to be shown before the society. Further examination would no doubt show that the glandular downgrowths were in reality derived from the uterine mucous membrane.

Dr. R. Hamilton Bell in a paper on Torsion of the Pedicle in Hydrosalpinx and other Morbid Conditions of the Fallopian Tube, dealt first with the literature of the subject. 12 cases of this rare accident in addition to 41 collected by Cathelin were recorded. A full account was given of a case under Dr. Bell's own observation. The general problem of torsion of the abdominal viscera was discussed. It was pointed out that the particular conditions necessary to the production of this accident were much more frequently present in cases of hydrosalpinx than in other forms of tubal disease. Short notes followed on the two varieties of torsion, acute and chronic; the direction of rotation; and the results of the twist. The influence of age and pregnancy was also discussed. The paper concluded with a consideration of the more clinical aspect of the cases. The close approximation of the symptoms to those of a twisted ovarian pedicle was recognised and the fact was noted that a correct diagnosis previously to operation had never yet been made. But it should be at least suggested when the following conditions were present: a fluctuating abdominal tumour of irregular shape, not rising above the umbilicus, associated with paroxysmal attacks of pain, culminating in a very severe attack with vomiting and constipation, and if the tumour had been observed before increase of size, tenderness, and some loss of mobility. The treatment consisted of removal of the twisted tube by abdominal section and Dr. Bell thought that the other tube should be dealt with conservatively whenever possible.—Mr. Bland Sutton regarded the diagnosis of this condition as practically impossible. It was a fact that Fallopian tubes when distended with simple fluid, pus, blood, or even when gravid, did twist their pedicles, but it was very difficult even to attempt to frame a plausible theory to explain it; this could be attributed in great measure to their profound ignorance of the statics and dynamics of the peritoneal cavity.—Dr. F. J. McCann referred to a case of tubal gestation with twisted pedicle which he had published. —Mr. Alban H. G Doran considered that diagnosis must be impossible in many cases and that therefore this condition was often overlooked and commoner than clinical records would lead them to believe. Again, it seemed probable, for mechanical reasons, that it was easier for a tube than for an ovarian tumour to untwist itself after axial rotation. Tubal torsion to any appreciable degree was rarer than torsion of the ovarian pedicle because the dilated tube soon became fixed by adhesions, whilst many ovarian cysts did not become adherent to neighbouring structures till after torsion.—Dr. Lewers referred to a case of his own of pyosalpinx with torsion of the pedicle.—Mr. J. H. Targett referred to two cases of tuberculous pyosalpinx in which a similar accident had occurred. He thought that in tuberculous disease the conditions were specially favourable for torsion to occur and that practically all cases of pyosalpinx with subsequent twisting of the pedicle were tuberculous in character.—Dr. Bell replied.

Society of Medical Officers of Health.—A meeting of this society was held on April 8th, Dr. J. Groves, the President, being in the chair.—Dr. J. Howard-Jones read a paper on the Control of Measles which was an appeal for some form of concerted action for checking the spread or reducing the mortality of a disease which caused no fewer than 13 000 deaths annually in England and Wales and which had been uninfluenced by sanitary improvement for the past 50 years. In many towns closure of schools was never resorted to, in others only when the attendance had been so seriously reduced that it could not be deemed in any sense a preventive measure, and in some it was confined to the infant departments. So with regard to Sunday schools, the practice was equally various: in one town only—viz., Reading—had the corporation Parliamentary powers of closure. Notification was compulsory in a few towns, voluntary in others, but unknown in most. In a large number it had been tried but abandoned. From Dr. Theodore Thomson's report to the Local Government Board it appeared that from 90 to 95 per cent. of the deaths from measles were of children under five years of age, that the greatest fatality was during the second year, but that the incidence of the disease was heaviest in the third, fourth, and fifth years. It would thus be understood why it was that in a number of schools examined by Dr. J. Kerr, medical officer to the London School Board, 75 per cent. of the children over five years had already had the disease. It was therefore clear that schools being the centres from which every epidemic spread and the great majority of the cases, with practically the whole of the deaths, being of children under five years, the attendance of such infants—in fact, of babies—was directly responsible for the greater number of the 13,000 deaths. Their exclusion might not reduce the total amount of measles since the infectivity of the disease was such that sooner or later nearly everyone contracted it, but it would by delaying the age of exposure and attack probably lengthen the intervals between epidemics and reduce the mortality. Infants might still contract it from elder children in the same house but while the family consisted of young infants only they would not be exposed to infection. The attendance at school of infants under six years was unnecessary and injurious; they were incapable of "schooling," and the confinement and impure air of the school room were hurtful to their health and development. The £1,250,000 spent on the so-called education of 610,989 infants under five years of age in elementary schools would be available for higher education and research work, or, say, £1,000,000 for this and £250,000 for the medical inspection of schools and the prevention of disease, while the rates would be relieved for some years from the cost of much school extension, since 14 per cent. of the existing accommodation would be set free for older children. Their attendance was not required by the Elementary Education Act but would be encouraged by the school authorities so long as it counted towards the Government grant. The alleged advantages were far outweighed by the disadvantages and the fact that deaths from measles were confined to the children of the poor was not due, as commonly held, to neglect and exposure during convalescence, for they occurred mostly in the first week, but to their being exposed to infection at the ages of greatest suspectibility and fatality of the disease.—Dr. M. K. Robinson said that the experience of notification in Dover had been very satisfactory. In the seven years prior to its adoption the deaths had averaged 180 per annum and were rising, while since that time they had averaged 81.—Mr. T. W. H. Garstang said that his experience was confined to rural districts but he had repeatedly found that by closing schools so soon as there was evidence of an outbreak it was suppressed before a month had passed, whereas when he failed to obtain the order the disease would persist for much longer periods.—Dr. R. Dudfield maintained that all measures were alike useless so long as those hotbeds of infection—the baby class rooms—were permitted, though something might be done by visitation by lady inspectors, and so on. The Public Health Act, 1875, did not define dangerous infectious disease and he thought that it was in the power of an authority to constitute measles one; at any rate, a test case was desirable.—Dr. S. Davies gave his experience of experiments in the closure of schools in a large urban district where the mortality from being one of the highest in the metropolitan area was now one of the lowest, and asked why the mortality from whooping-cough had diminished while that from measles did not.—Dr. J. F. J. Sykes considered that the rise in the mortality from measles which occurred in the "eighties" was due entirely to the lowering of the school age.—Dr. A. Newsholme had had cards printed with the names of all ordinary infectious diseases, on which the teachers inscribed the name of the pupil, scoring out those from which the child had suffered, and on the appearance of which in the school he or she need not be excluded. Such exclusion of the susceptible only was far more rational than closure to the immune and susceptible alike.

Glasgow Southern Medical Society.—A meeting of this society was held on March 31st In the absence of the President the chair was occupied by Dr. J. Coulson Howie.—Dr. T. K. Monro read a paper on Alcohol in Medicine, in the opening part of which he referred to the changes that had occurred in the principles and practice of medicine and in the use of drugs. He instanced potassium bromide as an example and referred to its introduction for the reduction of splenic enlargement, while at the present time it was principally used in the treatment of epilepsy. Quite a revolution, the speaker declared, had occurred in the use of alcohol in medicine. He referred to the old treatment of fevers by powerful stimulation by alcohol and gave as an example of this treatment the practice of R. Bentley Todd who was in the habit of administering great quantities of alcohol in such cases; in one case of a girl, 18 years of age, suffering from enteric fever and pneumonia he gave as much as 48 fluid ounces in the 24 hours. This practice was now obsolete and reference was made to the part which Sir W. T. Gairdner took in the abolition of it. Speaking of alcohol as a food, Dr. Monro declared that there was no evidence to support such an idea. The fact that alcohol was not recoverable from the excretions, he declared, was no evidence of its taking the part of a nutrient. In the process of digestion alcohol was split up into carbon dioxide and water and so in reality was a heat producer, and by preventing the oxidation of fat it became also a fat producer. From the fact,' discovered by experiment, that alcohol diminished the systole of the heart and increased the diastole it was proved not to be a cardiac stimulant. In the failing heart of cardiac valvular disease alcohol was declared to be useless. The transient rise of blood pressure noticed after the exhibition of alcohol arose from the reflex action of tissue irritation. When sufficiently diluted alcohol did not cause any rise of blood pressure.—Following Dr. Monro, Dr. J. W. Findlay made some remarks on the action of alcohol on the pulse-rate, the temperature, and various morbid conditions. On the administration of alcohol there was a very slight and transient increase of the pulse-rate; on the temperature its power as an antipyretic was of no importance. Given in large doses, however, it caused great depression of temperature from vaso-motor relaxation, as was seen in cases of acute alcoholic intoxication. In hot climates the free use of alcohol predisposed to sunstroke. Dr. Findlay referred to its use in cases of fainting, neuralgia, great cold, and dysmenorrhœa; in the last-mentioned condition he considered it a dangerous remedy to advise, as there were other means of relief much safer.—Dr. Howie, *Dr. D. Macgilvray, and Dr. John Stewart took part in the* discussion which followed, and Dr. Monro and Dr. Findlay were cordially thanked for their contributions.

Reviews and Notices of Books.

Adeno-Myome des Uterus. By THOMAS CULLEN, Assistant Professor in the Johns Hopkins University and Gynæcological Assistant in the Johns Hopkins Hospital in Baltimore. With 45 illustrations in the text. Berlin: August Hirschwald. 1903 Pp. 91.

Dr. Cullen's monograph is based upon a number of specimens of adeno-myomatous tumours which he has observed at the Johns Hopkins Hospital at Baltimore. The cases are very fully described and the histological details are illustrated by numerous figures. As the author points out, attention was first drawn to this class of tumours by the work of von Recklinghausen in 1896 and since then a number of cases have been recorded in the literature of the subject. In the majority of instances these tumours consist of a uniform diffuse myomatous thickening of the innermost layers of the uterine musculature into which processes of the hypertrophied mucous membrane of the uterus grow down, thus giving rise to the presence of glandular elements and cystic spaces in the middle of the tumours. They may be divided clinically into three classes—those in which the form of the uterus is not altered and those in which the tumours are either subperitoneal or submucous. One of the characteristic features of the growths is that, unlike the ordinary form of fibroid tumour, they tend at their margin to pass imperceptibly into the rest of the muscular tissue of the uterus without any very clear line of demarcation. The author conclusively shows that in the great majority of the cases the glandular elements are derived from the ingrowth of the mucous membrane of the uterine cavity into the tumour. The view of von Recklinghausen that the glands in these tumours are derived from the remains of the Wolffian bodies is not accepted by Dr. Cullen. He comes to the conclusion that in all cases of adeno-myomata of the uterus in which the glandular elements are similar to those of the uterine mucous membrane and are surrounded by a stroma similar to that surrounding the uterine glands, they are derived from the glandular elements of the uterine mucous membrane or from that of the Müllerian ducts, whether the tumours are interstitial, subserous, submucous, solid, or cystic. In the case of the adeno-myomata arising in the uterine horns, Dr. Cullen attributes the presence of gland elements to outgrowths from the uterine mucous membrane, while in the case of similar tumours arising from the tubal portion of the cornua of the uterus—viz, that containing the interstitial portion of the tube—the glandular elements are probably derived from the mucous membrane of the tubes. Adenomyomata of the round ligament are considered to arise from aberrant portions of the Müllerian ducts. In support of this view is the fact that during menstruation the spaces in these tumours become filled with blood and the membrane lining them resembles very closely the menstruating mucous membrane of the uterus. Adenomyomata are essentially benign tumours and two very interesting cases are recorded by the author in which in spite of the fact that the tumours were imperfectly removed no recurrence took place and the patients recovered. No doubt in the majority of cases these tumours are mistaken for fibro-myomata of the uterus, a diagnosis by clinical examination alone being impossible. They are not infrequently associated with fibro-myomatous tumours, while Dr. Cullen has met with cases of an adeno-myoma occurring together with a squamous-celled carcinoma of the cervix, with an adeno-carcinoma of the body of the uterus, and of an adeno-carcinoma of the body of the uterus arising in an adeno-myomatous tumour. In 15 of the cases the appendages were carefully examined but no relationship could be detected between the presence of these tumours in the uterus and any lesions of the tubes or ovaries. Dr. Cullen's work is an interesting contribution to our knowledge of an important and little known group of tumours.

Blood Pressure in Surgery: an Experimental and Clinical Research. By GEORGE W. CRILE, A.M., M.D., Professor of Clinical Surgery, Western Reserve Medical College. London and Philadelphia: J. B. Lippincott and Co. 1903. 8vo, pp. 422. Price 18s. net.

To this work the Cartwright Prize of the Alumni Association of the College of Physicians and Surgeons, New York City, was awarded last year. It contains the results of 251 experiments on 243 animals. It was undertaken chiefly with a view of determining the nature of shock in surgical operations and the best means of removing its effects. The experiments were made on dogs which were first rendered insensible by an anæsthetic. The trachea was then opened and a cannula was introduced and tracings of the blood pressure were taken. The animals were reduced to the condition of surgical shock or collapse by blood-letting, by removing the integument, by dividing the cardiac nerves, by stimulating the sciatic nerve electrically, by manipulation of the intestines and crushing the paws or the testes, and by other methods; and then various substances were subcutaneously or intravenously injected, such as alcohol, nitroglycerine and amyl nitrite, digitalis, strychnine, normal saline solution, adrenalin and morphine, and various combinations of these drugs, with a view of testing their influence in modifying the blood pressure and thus of preserving life or of acting injuriously. The effects of increased atmospheric pressure both when exerted on the inspired air and when applied to the surface of the body were investigated and, finally, experiments were made on the changes in the blood pressure induced by various operations such as those on the head, mouth, neck, thorax, abdomen, genito-urinary system, spinal column, and other parts. The observations which are here recorded are of great practical importance and we venture to mention a few of them, though the book itself should be studied by those whose daily avocations bring them frequently into relation with shock. In the case of alcohol in animals suffering from shock, however induced, the injection of a moderate dose usually produced further depression and in some instances a considerable dose, when the state of shock was intense, was followed by almost immediate death. The injection of nitroglycerine and amyl nitrite also increased shock. The action of digitalis in animals suffering from shock, either in the form of fluid extract, tincture, or as pure digitalin in solution, caused a rise in the blood pressure, but they did not live so long as control animals—i.e., animals reduced to the same condition of shock but not treated with digitalis. In regard to strychnine it was found that in any degree of shock after the administration of a therapeutic dose of strychnine the animals passed into deeper shock. Adrenalin, in regard to which the author gives an excellent historical account, under the most diverse conditions and degrees of shock invariably caused increase of blood pressure and prolonged the action of the heart. In another series of experiments it was found that digitalis and strychnine supplemented each other very well, the strychnine heightening the excitability of the medulla and spinal cord and the digitalis augmenting the blood pressure. The author draws the important conclusion that the treatment of shock by the most commonly employed stimulation—namely, strychnine, brandy, digitalis, and nitroglycerine—is injudicious and improper, since it produces systemic confusion in the animal.

There is an important section dealing with the subject of resuscitation of animals apparently dead. In this section the results of many experiments are summarised and the statement is made which is worth recollecting that animals apparently dead for 15 minutes may be and were brought back to life by the combined effect of artificial respiration, rhythmic pressure upon the heart, and the infusion of adrenalin. When the blood pr[illegible] again, it seemed probable, [illegible] the heart b[illegible]ressure rose to 30 millimetres Hg or more restored [illegible]egan to beat and the blood pressure was rapidly press[illegible] The various methods of determining the blood [illegible]ure in the human subject are given and are illustrated y many woodcuts. The average blood pressure in the human ubject seems to be between 110 and 150 millimetres, varying nder many different conditions, sometimes being estimated t 200 millimetres and sometimes at less than 100 millimetres. n conclusion, the essential phenomenon of shock is held by r. Crile to be a diminution of blood pressure but he shows y very satisfactory arguments that this diminution is not ue to the failure of the heart or of the cardiac mechanism ut to a loss of peripheral resistance which is again the onsequence of exhaustion or breakdown of the vaso-motor entres. The best means of combating the condition of hock in whatever way it [illegible] be produced is by the intravenous injection of a saline [illegible]ion containing one par[illegible] in 0,000, or one part in 100,000, [illegible] adrenalin. An additional means is to be found in pneumatic pressure applied to he exterior of the body by means of a rubber dress. Very reat credit is due to Dr. Crile and to the gentlemen by whom e was assisted for the originality and precision of the xperiments recorded. It is obvious that the results obtained have an important bearing on practice.

Studies in Heterogenesis. By H. CHARLTON BASTIAN, M.A., M.D. Lond., F.R.S., &c. With 815 illustrations from micro-photographs and 19 plates. London: Williams and Norgate. 1903. Pp. xxxvii.-345. Price 31*s.* 6*d.*

IN his studies in heterogenesis Dr. Charlton Bastian sets forth at length the evidence on which he bases his belief in the contention which he has so long upheld that the lower orms of life—bacteria, amœbæ, monads, and infusoria—are interchangeable. In other words, Dr. Bastian holds that aggregates of bacteria do not breed true but in their offspring are transformed into what the present-day world is prone to regard as distinct and non-interchangeable forms of life. A slight step further brings Dr. Bastian to advance evidence of the *de novo* origin of many lowly organisms and, owing to its important medical bearings, to deduce from this evidence conclusions which, if rightly established, must of necessity cause the whole fabric of bacteriology, infection, and hygiene to fall upon, and to annihilate, the multitude of investigators who have helped to build upon the foundations laid by Pasteur and to cause the name of Pasteur himself to be erased from the roll of fame.

To review this elaborate book at length would be but to attempt to fight over again the battle ably fought, and we believe won, by Darwin, Pasteur, and their disciples. For this we have no space, nor is it needful to do so. The story is, or ought to be, a matter of common knowledge. It is easily accessible in many interesting volumes, in which the development of the accurate bacteriological methods of the present day can also be traced. No doubt advocates of the occurrence of spontaneous generation and heterogenesis will regard this attitude as an untenable *a priori* standpoint. To one schooled in the modern perfected and unequivocal methods for the *pure* cultivation of bacteria it is, however, the only light in which the results obtained by methods discarded by bacteriologists themselves can be regarded. The antiquated methods which still find favour in attempts to re-establish the *de novo* origin and interchangeability of lowly forms of life find no place in modern bacteriological technique. In this attitude bacteriologists are but extending to the advocates of spontaneous generation the treatment which they mete out to one another and against which no bacteriologist will be found to protest.

The methods of modern bacteriology have been devised to exclude or to obviate the errors arising from "outside infection" and the notoriously deceptive appearances suggestive of transition forms of cell life. If bacteriologists [illegible] detect in the results of other members of their calling features which are incompatible with cleanness and accuracy of metho[illegible] those results are discounted [illegible] in the same way as those [illegible] not obtained by Dr. Bastian are received with scepticism a[illegible]nd the erring or would-be authority on bacteria finds t[illegible]hat his results fall upon unsympathetic ears if he be fort[illegible]unate enough to find them escape denouncement as futile an[illegible]d fatuous efforts. We do not doubt that Dr. Bastian ha[illegible] taken all the care that his methods have allowed. [illegible]e are aware of what passes in fluid media containing lo[illegible]ly organisms and can fully appreciate the phenomena [illegible]hich he has so carefully depicted in some 815 reproduction[illegible]s of micro-photographs but we hold that a serious chal[illegible]lenge to the claims *made on behalf of modern* bacteriolog[illegible] is not the outcome of his patient labours, for [illegible]reason [illegible] that the limitations of the methods the simple[illegible] employed [illegible]use him [illegible] to *magnify* the importance of what the bacterio[illegible]logist with better methods regards as avoidable, and therefo[illegible]e unjustifiable, [illegible] sources of error. The book cannot fail [illegible]o be perused wi[illegible]th interest. *It is written with* great [illegible] acumen and will be eas[illegible]ily intelligible to all who wish to poss[illegible] the best possible sta[illegible]tement of the case against the claim[illegible] modern bacteriology [illegible] and unicellular biology.

LIBRARY TABLE.

Stretcher Drill, Illustrated. Second edition. Including the new band-seat, wagon, and railway wagon drills, compiled from [illegible] Manual of the Royal Army *Medical Corps* 1904 Regu[illegible]ns for Army Medical Services, *Field Service* Manual A.M.S., King's Regulations, &c. By Major J. J. DE ZOUCHE MARSHALL (p.s.), Hon. Assoc. Order of St. *John* of Jerusalem in England, commanding *East Surrey Vol. Inf.*

Brigade Bearer Compy., Army Medical Reserve of Officers, late of 1st Cinque Ports R.V.C. and 3rd V.B. East Surrey Regt., Ambulance Instructor of London Metropolitan Police. Published by permission of His Majesty's Stationery Office. 1904. Printed at the office of T. W. Childs, at 10, Broad-street, Teddington. Published by the author at Shortwood, Teddington, Middlesex. Pp. xviii.-110. Price 3s.—This is the second edition of "Stretcher Drill, Illustrated," the first of which we noticed in THE LANCET of July 2nd, 1898, p. 32. The author tells us that he has been encouraged to publish a second edition by the favourable opinions which have been expressed by medical officers of both the Volunteer service and of the Royal Army Medical Corps in regard to the usefulness of his first venture. The nature of the little treatise, which is mainly of a technical kind and is profusely illustrated by engravings and diagrams, is sufficiently set forth in its title. In addition to practical descriptions of stretcher, ambulance wagon, and railway wagon drills the work contains much information on a variety of other subjects likely to prove useful to all having to do with bearer work and the transport and management of sick and wounded. A cardboard "stretcher and patient" issued with the book, it may be added, will be found useful in serving the purpose of learning the drill at home.

Essay on the Irregularities of the Teeth, with Special Reference to a Theory of Causation and the Principles of Prevention and Treatment. By J. SIM WALLACE, D.Sc., M.D. Glasg., L.D.S. R.C.S. Eng. London: The Dental Manufacturing Co., Limited. 1904. Pp. 162. Price 5s net. —This book is a collection of essays which have appeared in the columns of the dental journals. The author freely criticises the views generally accepted with regard to the etiology of irregularities of the teeth and advances a theory of his own; indeed, the keynote to the book is found in the following quotation from the preface. He says: "My studies had so thoroughly convinced me that acquired characters were not transmitted I felt that some other explanation could be made which would account for the diminution in size of the jaws and for the irregularities of the teeth. The idea struck me that there might be an intimate relation between the size and growth of the tongue and the size and development of the jaws, and that this would best explain the facts without any assumption of the inheritance of acquired characters. The facts with which I was acquainted were so easily harmonised by the hypothesis that in a few hours I had roughly sketched out in my mind the theory that I am about to explain." There is undoubtedly a good deal in this book to stimulate thought on the subject but we think if the author had been acquainted with more facts he would have found that they did not all harmonise with his hypothesis. In a work, too, aiming at a scientific study of the question it is a little strange to find illustrations of the type seen on pages 96 and 97. The author sharply criticises Mr. C. S. Tomes's views on selective breeding and supports his own views by pictures apparently from fashion plates, one being reproduced by permission of the *Lady's Pictorial* and the other by Messrs. Harrods. The author gives them as examples of faces with small oral orifices but ample buccal cavities—on what grounds he does not state but to our mind one figure suggests a case of superior protrusion and the other a contracted upper jaw from which the canines have been removed.

The Public Schools Year book, 1904 London: Swan Sonnenschein and Co., Limited. Pp. 568. Price 2s. 6d.—This useful work, which is now in its fifteenth year of publication, was "founded by three public school men—Eton, Harrow, Winchester"—and we learn from the preface that it was the intention of the editors "to include only the great historical public schools along with the more important Victorian schools which have so ably maintained the traditions of the earlier foundations." Gradually, however, the scope has been widened and now the only limit drawn is that a school must be connected with the Headmasters' Conference. Next year, indeed, it is the wish of the editors to deal with the leading girls' schools. The book contains a great deal of information as to the various schools therein included and two new features of this year's issue are an engineering appendix and a musical appendix which give full details as to instruction in these two branches of science and art.

Memoranda on Infectious Diseases for the Use of School Teachers. By JAMES W. ALLAN, M.B. Glasg. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co, Limited. 1904. Pp. 23 Price 6d.—This little book was originally written for teachers under the Cathcart school board and in the words of the author is meant to be brief and fragmentary. In no profession other than the medical is the ability to recognise the signs of infectious disease so important as in that of the teacher, for a child at school suffering from some infectious disorder, if not promptly isolated, is almost bound to infect his fellows. Dr. Allan gives very plain and simple directions as to the signs and symptoms which may lead the teacher to suspect that a child under his charge is suffering from infectious disease. At one point, however, perhaps, he is a little too optimistic and that is where he says that a child "may return to school three weeks after appearance of rash," the rash in question being that of measles. It would have been well had this statement been qualified by the proviso that all desquamation should be at an end and that the general health of the child should be satisfactory. In some cases four weeks may be necessary. Apart from this point the directions given are admirable.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Vol. XXXI., No. 1. London: C. J. Clay and Sons. March 29th, 1904. Price 4s.—The articles contained in this number of the *Journal of Physiology* are as follows: 1. The Time Relations of the Photo electric Changes produced in the Eyeball of the Frog by means of Coloured Light, by Francis Gotch, F.R.S., with seven figures in the text. The records for the comparison of the time relations were obtained by means of the capillary electrometer. The red light response is characterised by a long latency period equalling three tenths of a second and a strength of 0·0004 volt. With green and white light the latent period was two-tenths of a second and the maximum response averaged over 0·0005 volt. The response to violet light was $\frac{28}{100}$ths of a second and was of low intensity, averaging only 0 00024 volt. The response to sudden darkness had a latency of two-tenths of a second and is not easily obtained after violet illumination unless this has been maintained for eight seconds or more. The results appear to be in accordance with the Young-Helmholtz theory of light as modified by Maxwell which assumes three distinct colour reactions—*viz.*, red, green, and violet. 2 On Protagon, Cholin, and Neurin, by W. Cramer. Mr. Cramer believes that protagon is not a mixture of different substances but can be isolated. 3 The Function of the Hyaloid Canal and some other New Points in the Mechanism of the Accommodation of the Eye for Distance, by T. P. Anderson Stuart, with nine figures in the text. 4. Contribution to the Physiology of the Thymus, by D. Noel Paton and Alexander Goodall, with one figure in the text. The authors of this article found that in guinea-pigs removal of the thymus is accompanied by a decrease in the number of all varieties of the leucocytes, which decrease in number lasted about two months. The removal of this organ diminished the resisting power of the animal to the action of the toxins of staphylococci and streptococci but not to the toxin of diphtheria.

Scottish Medical and Surgical Journal.—The first four original articles in the April number are as follows: Chronic Intestinal Obstruction caused by Annular Stricture of the Large Intestine, by Mr. David Wallace; Referred Pains, by Dr. William Bruce; a case of General Streptothrix Infection, by Dr. Stuart McDonald; and a case of Pancreatic Infantilism, by Dr. Byrom Bramwell. Abstracts of three of them have already appeared in our columns in the reports of the meetings of the Edinburgh Medico-Chirurgical Society. The paper on Streptothrix Infection gives a very full account of the bacteriology and pathogenic relations of the organism; it is illustrated by two finely-executed coloured plates and several photoprints of microscope fields. Among the summaries of recent literature much information of interest at the present time is given in a paper by Dr. Harry Rainy on Blondlot's "N" Rays. It was in a communication made to the Paris Academy of Sciences on March 23rd, 1903, that M. Blondlot of Nancy announced his discovery of these rays which pass through aluminium but differ from Roentgen's x rays in several respects. The articles published on the subject are to be found chiefly in the weekly *Comptes Rendus* of the Academy of Sciences. Some English investigators on repeating the experiments made in France have not succeeded in obtaining confirmatory results. Some physiological relations of these rays have been described and have been referred to in our columns more than once during the present year.

Caledonian Medical Journal.—Several of the Stewart Celtic Prize Essays have from time to time been published in this journal and one of them forms the opening article in the April number. It is on Old Highland Therapy, is by Mr. Henry Whyte of Glasgow, and naturally contains some Gaelic, both in prose and verse. Dr. T. D. Greenlees, medical superintendent of the asylum at Grahamstown in Cape Colony, writes on the Circulatory Apparatus in General Paralysis of the Insane. He considers that in this condition the pulse presents some characteristic features which may be demonstrated by the systematic use of the sphygmograph. In an article on Medico-legal Experiences Colonel Kenneth Macleod, I.M.S., refers to gynæcological troubles arising out of child marriages in India. The annual meeting of the Caledonian Medical Society will be held on July 22nd in Edinburgh.

Liverpool Medico-Chirurgical Journal.—This journal is published half yearly. The present issue is dated January, 1904, contains 220 pages, and is mainly a record of 28 papers read and many specimens exhibited at the meetings of the Liverpool Medical Institution from January to April, 1903. Several of these communications have therefore been mentioned in our reports of these meetings. The great majority of the papers are on surgical subjects and several are accompanied by illustrations. There are four original articles, the titles of which are: Treatment of Asthma, by Mr. Colin Campbell; Treatment of Prostatic Obstruction, by Mr. D. Douglas-Crawford; Chronic Interstitial Nephritis, by Dr. J. H. Abram; and the Vestiges of Syphilis, by Dr. F. H. Barendt.

The Calcutta Practitioner: a Medical Journal. Calcutta: Published by the City Book Society. Annual subscription for India, 5 Rs.; for foreign countries, 8*s.*—We have received the first two numbers (January and February, 1904) of the above-named journal. We are glad to welcome its appearance, for it may meet a want, as it is intended for circulation among the native members of the medical profession in Bengal. As the editor writes in the introduction to the first number, "No apology is necessary to justify the appearance of a new medical journal in a land where such periodicals are only conspicuous by their scarcity." What is primarily sought for in this new publication is to provide a medium of circulation for the records of the valuable experiences of the isolated units of the medical profession of Bengal. The editor writes with reference to tropical medicine that the clinical phenomena connected with such diseases may be studied much more advantageously in India, where cases are so numerous and varied, than in the schools of tropical medicine in Great Britain. All the articles are written by native practitioners and the text contains many examples of the modes of expression and of the usual mistakes which are familiar to those who are accustomed to English as spoken by the "baboo." The January issue contains a paper on Adrenalin Chloride in Plague and other Diseases, by Rai Bahadur Kailaschandra Bose, L.M.S., C.I.E. This article is worth reading; the author says that adrenalin, given in any stage of plague, maintains the heart and pulse admirably well and brings down the temperature; that its effect in pneumonic and intestinal plague is far from encouraging, but that in bubonic plague, uncomplicated with pulmonary and intestinal troubles, it is a sovereign remedy. The second number, issued in February, contains an interesting paper on the Effects of Mental Impressions of the Mother on the Embryo, by Haridhan Dutta, L.M.S., and also Dr. Bully Chunder Sen's address to the Calcutta Medical Club, delivered at its third annual general meeting. The address deals chiefly with the prospects of the native graduates in the Government service and the grievances of assistant surgeons. Among the contents are Clinical Notes and Records, Reviews of Books, and Remarks on Current Medical Events and on Current Medical Literature. The general get-up and the printing of the journal are very creditable.

Analytical Records

FROM

THE LANCET LABORATORY.

(1) KEPLER MALT EXTRACT WITH HÆMOGLOBIN; (2) MANGANESE AND IRON CITRATE (SOLUBLE) WITH QUININE; AND (3) MANGANESE AND IRON CITRATE (SOLUBLE) WITH STRYCHNINE.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

1. THE assimilation of iron in the form of hæmoglobin is now established and the latest contribution upon this subject appeared in a paper by Dr. W. D. Halliburton.[1] The results of all observers show that the administration of hæmoglobin improves considerably the condition of the blood with a resulting gain in health and strength. Hæmoglobin is very favourably exhibited in the Kepler Malt Extract. In this form it is agreeable to take, besides which the malt extract itself is a nutrient and helps the digestion of starchy foods. On the whole this combination may be regarded as a valuable therapeutic addition and its use is specially indicated in anæmia, chlorosis, and general debility. We found the preparation to be highly active in converting starch into sugar. A dilute solution gave the characteristic hæmoglobin spectrum; the moisture amounted to 21·41 per cent. and the ash to 1·49 per cent., the latter containing iron and an abundance of phosphate. 2. The preparation of manganese and iron citrate in scale form containing quinine is an obviously valuable combination, as is also that (3) which contains strychnine together with the scale preparation of manganese and iron citrate. We have confirmed on analysis the amounts of the metals and alkaloids stated. In preparation (2) of quinine the manganese amounts to 7 per

---

[1] Brit. Med. Jour., April 9th, 1904.

cent, the iron to 14 per cent, and the quinine to 15 per cent. In the strychnine preparation the quantities of manganese and iron respectively are the same with 1 per cent. of strychnine. Both preparations may be had in the form of tabloids.

ALE AND STOUT.

(BARCLAY, PERKINS, AND CO, LIMITED, PARK STREET, SOUTHWARK, LONDON, S.E)

On analysis the light bitter ale (No 1) gave the following results: extractives, 4·79 per cent.; mineral matter, 0·23 per cent.; alcohol, by weight 3·12 per cent, by volume 3·90 per cent, equal to proof spirit 6 84 per cent.; maltose, 2·05 per cent.; fixed acidity calculated as tartaric acid, 0·112 per cent.; and volatile acidity reckoned as acetic acid, 0 09 per cent. This is a well-brewed light ale and a genuine malt liquor bittered with hops. It was in excellent condition. The analysis of a sample of stout marked No. 2 furnished the following results: extractives, 5·10 per cent.; mineral matter, 0·30 per cent.; alcohol, by weight 5·25 per cent., by volume 6·55 per cent., equal to proof spirit 11·49 per cent.; maltose, 2·36 per cent.; fixed acidity reckoned as tartaric acid, 0·20 per cent.; and volatile acidity reckoned as acetic acid, 0·06 per cent. As will be seen from this analysis this is a light form of stout free from acidity and containing only a moderate amount of malt extractives. No. 3 B.S. stout gave the following results on analysis: extractives, 8·40 per cent.; mineral matter, 0 45 per cent; alcohol, by weight 4·00 per cent., by volume 5·00 per cent., equal to proof spirit 8·77 per cent.; maltose, 3 10 per cent.; fixed acidity reckoned as tartaric acid, 0·22 per cent.; and volatile acidity reckoned as acetic acid, 0·06 per cent. The amount of malt extractives is characteristic of a stout described as nourishing, while the alcoholic strength is relatively low. The stout was in good condition and free from acidity. No 4 is an export stout which gave the following results on analysis: extractives, 7·85 per cent; mineral matter, 0·35 per cent.; alcohol, by weight 7·27 per cent., by volume 9·04 per cent., equal to proof spirit 15·85 per cent; volatile acidity reckoned as acetic acid, 0·11 per cent.; fixed acidity reckoned as tartaric acid, 0·24 per cent.; and maltose, 2·50 per cent. As will be seen, this export stout contains more alcohol than does the previous specimen. It is an excellent example of this description of malt liquor. No. 5 is a specially brewed stout intended for exportation to the Russian and North German markets. The analysis was as follows: extractives, 9·95 per cent.; mineral matter, 0 55 per cent.; alcohol, by weight 9·36 per cent., by volume 11·61 per cent., equal to proof spirit 20·35 per cent.; maltose, 2·78 per cent; volatile acidity reckoned as acetic acid, 0·15 per cent.; and fixed acidity reckoned as tartaric acid, 0·35 per cent. This is a "vigorous" malt liquor containing a relatively high amount both of extractive matters and alcohol. It was ripe and mellow and in sound condition, showing no excess of acidity. We believe these malt liquors are thoroughly genuine and they are evidently brewed with care, judging from their excellent condition and flavour.

DIOXOGEN.

(THE OAKLAND CHEMICAL COMPANY, NEW YORK. BRITISH AGENCY, THOMAS CHRISTY AND CO., OLD SWAN LANE, LONDON, E C.)

It is surprising that pure solutions of peroxide of hydrogen have not found greater application in medicine than is the case, since while it is comparatively harmless it possesses very decided cleaning and antiseptic properties. Dioxogen according to our analysis is well suited for medical use in the form of spray for inhalation or local application of the throat or to be taken in definite doses internally since it is free from the common impurities of preparations of hydrogen peroxide. It contains only a trace of chloride. In spite of its proportion of available oxygen the preparation is fairly stable According to our analysis dioxogen contains just over 3 per cent of pure peroxide of hydrogen.

CRYSTALLISED DIGITALINE (NATIVELLE).

(WILCOX, JOZEAU, AND CO, 49, HAYMARKET, LONDON, S.W.)

Digitaline in the pure crystalline state is, of course, a perfectly definite principle and in this form the therapeutic efficiency of the alkaloid can be accurately gauged. It is important that drugs possessing such a powerful action as does digitaline should be pure and definite. The digitaline extracted and crystallised by the process discovered by M. Nativelle, a pharmacist of Paris, has been employed in medicine with uniformly satisfactory results which signify that it is therapeutically superior to ordinary digitaline preparations. The crystalline alkaloid may be prescribed in the form of granules each of which contains $\frac{1}{250}$th of a grain.

COD OLS AND CAST-OLS.

(COD OLS MANUFACTURING CO, 93, DYERS HALL-ROAD, LEYTONSTONE.)

These preparations consist of croquettes of chocolate and flavouring compounds containing a definite amount of castor oil or cod-liver oil, as the case may be. They are prepared with the view of overcoming the objection to the taste of the respective oils. Some amount of success has certainly been obtained in the case of the castor-oil preparation but we cannot say as much for the cod-ol which, in our opinion, is particularly nasty when an attempt is made to masticate it. After all, nauseous substances occupying any bulk are necessarily more rapidly swallowed in the fluid than in the solid form.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 15, 1826.

ON THE MEDICINAL PROPERTIES OF SPIDERS.

To the Editor of THE LANCET.

SIR,—Dr. Bright, in his last Lecture on the treatment of intermittents, recommended, on the authority of one of his pupils, the cobwebs of a peculiar kind of black spider, as a very efficient remedy for obstinate agues. Dr. Bright did not detail the particulars of their modus operandi, neither did he mention the manner in which they should be administered, or the dose necessary for a perfect cure, but he assured his pupils that this action was most salutary, and directly attributable to the medicinal properties, and not to their acting upon the mind as a charm. Several patients having been cured by them, who had not previously been apprized of the nature of the remedy. As the spider to which the docile Doctor has alluded is, I believe, of a very rare species, perhaps it might not be improper to suggest to him the employment of the animals themselves, and also their kindred species, which more abundantly inhabit our houses.

"Credat, Judæus Apella
Non Ego."

A MEDICAL PUPIL.

The black spider (*araneus niger*, *List. Hist.* 77, *Schrod.* 5, 337) was formerly officinal, and much celebrated for its febrifuge virtues. Wrapped in leather, and hung about the arm, it was supposed to be capable of averting the fit of a quartan, and when boiled in oil and instilled into the ears, of easing pain in those parts. *Dioscor. Lib.* 2, *cap.* 68—The country people, with whom the dicta of physicians are handed down by tradition, believe that a small quantity of spider's web, given about an hour before the expected return of an ague, and repeated in half an hour, will prevent its recurrence. The Indians of North America are said to employ spiders and their webs in the same way, and, *a priori*, there is no reason why the former, at least, should not possess medicinal properties as well as the cantharis; whether they do is another question.—ED.

New Inventions.

AN IMPROVED ADJUSTABLE COMMODE.

THIS commode admits of a variety of adjustments, in one of which it presents an entirely horizontal surface, as shown in Fig. 2 It will, therefore, sometimes be serviceable in cases where the bed-pan cannot be used. Its height can be adjusted to that of the bedstead. The seat is of a good size and shape, like an ordinary water-closet seat, instead of a small round hole as usually found in commodes, and it is so constructed that it can be slightly raised at the foot end and so prevent a patient from slipping down. The lid which forms the section for the support of the upper portion of the body can be placed horizontally or it can be raised to various heights so that a patient may sit upright or partially so. When raised it is retained in position by strong pieces of cable which form side supports so that it resembles an arm chair, as shown in Fig. 1. If a patient is too helpless to be supported in this way the lid can be folded back and an attendant can stand behind to give the necessary assistance. The section which forms the support for the lower extremities may either be maintained in the horizontal position, as shown in the illustration, or it may be folded down in order to allow the feet to be placed on a hassock. If desired it can be provided with a sliding foot-piece for this purpose. In cases where it is desirable to keep one leg only horizontal the section can be divided longitudinally so that one foot only is lowered. When not in use, the lower section hangs down in front and the upper section is folded over the seat, forming a useful bedside table. Messrs. Arnold and Sons of West Smithfield, London, E.C., are the makers of the commode.

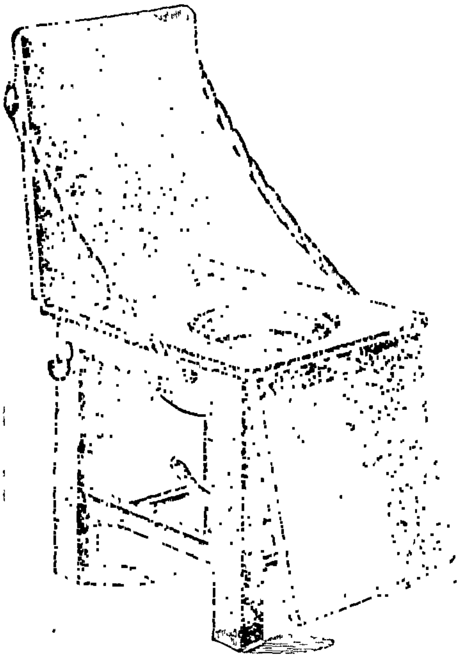

FIG. 2.

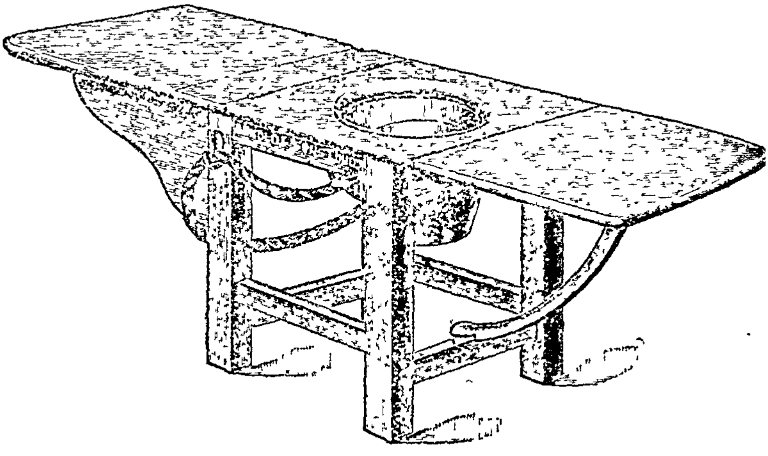

J. LIONEL STRETTON,
Senior Surgeon, Kidderminster Infirmary and Children's Hospital.
Kidderminster.

A REST FOR FLEXION OF THE THIGHS AFTER ABDOMINAL OPERATIONS.

HAVING noticed how invariably patients require their thighs flexed after abdominal operations and the frequency with which the usual pillows require readjusting, I venture to think that the rest shown in the illustration will be found useful. One of the chief points of the rest is that it provides a firm resisting plane for the thigh at an angle, the heels being allowed to touch the bed (Fig. 1). The rest is made in two sizes to suit long and short thighs. I have used these appliances for some time and they have given great comfort.

The wedge-shaped bolster (Fig. 2) is, I think, the ideal for hospital use where so many patients have to lie on their backs for a considerable period.

The bolster enables the shoulders to be slightly elevated, thus leaving the neck straight. As the patient progresses and is able to have a pillow as well it is even more comfortable, being less abrupt than the round bolster or two pillows.

Both the leg rest and the bolster have been most carefully prepared by Messrs. Down Bros., Limited, of St. Thomas's street, Borough, S.E., from whom they can be procured.

THE LANCET.

LONDON: SATURDAY, APRIL 16, 1904.

Medical Defence.

WE drew attention recently to a resolution that had been passed unanimously by the council of the Medical Defence Union in reference to the scheme formulated by a committee of the British Medical Association for medical defence. The motion was: "That this council resolves to do all in its power to maintain the integrity of the Medical Defence Union as at present existing." We have received a copy of a notice which has since been distributed to the members of the Medical Defence Union detailing the reasons which caused the council to come to the above decision. The document is temperately worded and the arguments are cogent and difficult to contest. And that is the point upon which we invite the attention of the medical profession.

The committee appointed by the British Medical Association to consider whether the Association should undertake defence work drew up a draft scheme, one of the paragraphs of which contained an "Invitation to the Medical Defence Union, to the London and Counties Medical Protection Society, and to the Medical and Dental Defence Union of Scotland, and other like societies engaged in medical defence, to merge themselves in the British Medical Association to form one professional department for the provision of medical defence." This was, indeed, a bid for that solidarity which we have always advocated. But the Medical Defence Union existing, as it does, as a *company limited by guarantee, cannot in any circumstances* merge or amalgamate itself into any other company or society, but must exist as a separate entity unless wound up voluntarily or compulsorily under the Companies Acts. The council naturally considers that to wind up and to liquidate a financially sound and successful company which has done for 19 years, and is steadily doing, excellent and valuable work, not only for its members but also for the medical profession generally, would be a waste of the funds of the subscribers. This procedure would involve a large expenditure and a needless sacrifice of the best interests of its members. The union has always performed its work well, has never spared any expense when its members were attacked, and in every way has gained their confidence. No wonder, then, that the council refuses to accede to a wish of the British Medical Association that the union should cease to exist as an entity and should merge itself in the defence department of the Association. In acting thus the council may be accused of acting in a purely selfish manner and of considering only its own interests and not those of the profession in general. This charge, however, cannot be substantiated. The union includes numerous practitioners who are not members of the British Medical Association and who, if the union were wound up, would either be cut off from defence or would have to regain the protection now afforded to them by becoming members of the Association and of its medical defence department. This, to our mind, is a forcible argument against the proposed scheme. According to the last return in Great Britain and Ireland, there are 30,409 registered practitioners, of which number about 15,000 (probably a liberal estimate) are members of the British Medical Association. There is no reason why these numbers should not increase, but it is in the highest degree improbable that the Association will ever include in its ranks every member of the profession, even though the scheme were carried out as it now stands, thus giving to the Association a monopoly of medical defence. Such a monopoly would, however, be only temporary, for another society would soon be formed by those who were not members of the Association. As we have frequently and strongly urged, we should like to see a coalition of the existing bodies engaged in Medical Defence. The experience of their executive committees or councils has now been extended and varied, their joint pecuniary position would be a very strong one, and the medical profession as a body would give more support to a coalition society than to two or more separate bodies.

We do not discuss the details of the scheme proposed by the British Medical Association. The question as to the necessity of altering the memorandum and articles of association in order to adjust the financial relationships between the Association and its new "department," the objects of that "department," and the manner in which it would be worked, are matters which concern the Association only and it would be meddlesome for us to offer any criticism. But the question of the extinction of the Medical Defence Union, the London and Counties Medical Protection Society, and kindred societies is a matter which affects the whole profession. The advantages of medical defence and protection are becoming more and more recognised. Several cases that have been heard recently in public have demonstrated to members of the medical profession that they are peculiarly open to risks which may suddenly involve them in legal proceedings or regrettable scandals. These snares are about the path of all and the only way to guard against them is to join a society for mutual defence. But it does not seem to us convenient that the only way to secure the necessary coöperation should be by joining the British Medical Association. That excellent body has multifarious aims and responsibilities, while the work of medical defence is peculiar. The British Medical Association does not include more than half the medical profession and the benefits of medical defence should be open to all. Lastly—and somewhat to repeat ourselves—the existing bodies have experience and the British Medical Association has none. Why should the medical profession prefer to consult those responsible for a new scheme? On the other hand the medical profession has a right to ask the Medical Defence Union and the London and Counties Medical Protection Society to amalgamate, because their utility would be much enhanced by combination.

Private Practice in Germany.

We are all accustomed to finding some aspect of the practice of medicine presented in a novel; nor is there of necessity anything objectionable in this, for it can hardly fail to be profitable to medical men to see themselves as others see them, even though, as has been sometimes the case, the vision of the spectator is distorted by ignorance or prejudice. Among smaller romancers the medical man is a favourite character, while nearly every great writer of fiction has taken occasion to sketch some worthy or unworthy member of the profession, often thereby pointing a confused moral or adorning an uninviting tale. Dickens has given us many medical portraits which, as a whole, in spite of the rampant caricature of some of them, afford valuable indications as to the social standing of the practitioners of the early Victorian era. Thackeray drew one medical man with splendid cruelty and Scott, George Eliot, and Trollope all made successes of medical portraits. There is not, however, in English literature any novel which as a serious study of the relations of the practising physician to his fellow citizens can be quite compared with a remarkable story by Heinrich von Schullern which has lately had a considerable vogue in Germany. It is entitled simply "Aerzte" (Doctors) and the author has in its production combined with an extensive knowledge of modern medicine the technique of the skilful and cultured novelist. The book deals with the experiences of a young medical man in a small town in Silesia and its pessimistic tone may possibly awake a sympathetic echo in the bosom of any struggling practitioner in this country who can find time to read it. The hero, Walter Hellmann, sets out upon his career full of faith in humanity and of enthusiasm for the work which he has undertaken. Little by little his hopes and aspirations are crushed by the meanness and selfishness of those with whom he is brought in contact, until at last he gives up his profession in disgust and despair and attains to some small measure of happiness as a tiller of the soil.

The picture of the middle and lower classes of Germans which is incidentally unveiled is a most unattractive one, but one which it is well should be put before medical practitioners in this country, that they may feel that many of the abuses under which they suffer are shared by their colleagues in Germany. Such a complete absence of delicacy, gratitude, or even common honesty as is displayed by Hellmann's patients would seem exaggerated if one had not met with similar instances in England, though perhaps nowhere in this country need the medical life be one of such unmitigated ugliness as the German author depicts. At the opening of the story, the keynote of which is struck in a quotation on the title page, "Die Leiden des aerztlichen Standes sind zahllos, seine Freuden gering" (the troubles of the medical profession are innumerable, its joys are few), Hellmann, a house physician at the St. Jacob's Hospital at Frankenstein, is seeking to obtain a post as parish medical officer in the neighbouring town of Ebenberg. A member of the senior staff, Dr. Tubinger, endeavours to dissuade him and in the course of sundry conversations gives him an inkling of what is in store for him. "Let me advise you to stay here at the hospital for a year or two," says his cynical counsellor. "You are, I know, rich in knowledge and devoted to your duties but these things count for nothing in private practice." He reminds Hellmann of an experience which the latter has had even while on the hospital staff. "Don't you remember what a scandal was made by the wife of one of our patients whom you with your scientific methods were treating without drugs? If you had only given that man a little water coloured with raspberry juice and had 'poison, with care' underlined on the label you would have been spared all that scene. How annoyed you were with that couple. A practising physician should have an especially thick skin, whereas yours is susceptible to the slightest impression. Remember, too, that here you have me to support you when folly and superstition assail you, but outside you will have to stand alone. Sound health and not too elevated sentiments are what you want. Keen sensibilities are most inappropriate and perilous qualities in the sphere which you propose to occupy." On another occasion he gives Hellmann further advice in the same strain. "You have before you the wearisome conflict with the stupidity, malice, and falsehood of the public, and especially of the female portion of it. Enemies of a not less dangerous character you may find in your fellow practitioners. In the medical profession, as in any other walk of life, gentlemen are not too numerous. But your greatest opponent will be yourself—that is to say, the most prominent features of your disposition. I repeat that for the medical craftsman no characteristic is more destructive to pleasure in his work than the possession of the finer feelings." Hellmann, however, is not to be discouraged. "The calling of the physician is," he tells himself, "one of the noblest. He is worthy to stand by the side of the soldier. In the fight against disease the doctor is as much a hero as is the soldier on the battlefield. The dangers, as well as the trials of body and soul, must be forgotten in the joy which the manifestation of one's love for humanity brings with it." Besides, there is a woman in the case and visions of domestic felicity cast a glamour over the future. A certain amount of canvassing has to be done and the task is not a pleasant one. The young man calls at the house of the mayor where he is shown but scant courtesy, for "the whole family, down to the youngest baby playing on the floor, considered that this person need only be treated with indifference." However, the appointment is obtained, and Hellmann leaves the hospital and begins a life of sordid drudgery which speedily dissipates such remnants of illusion as Dr. Tubinger has left him. He has at first some fastidiousness in the matter of receiving fees which, as an incident described in a letter to his betrothed shows, inspires little sympathy on the part of his clients. "The son of the landlord had the courage to allow me to pull out a tooth for him. I was more anxious about the affair than he was and took a fearfully long time, which extra trouble he acknowledged by offering me, in addition to the usual fee, a few coppers as *pourboire*."

Into the details of the story it is not necessary to enter. Nearly every chapter tells of something disagreeable which befalls the hero or the girl whom he has married. Such progress as he makes is counteracted by the malevolence of an influential woman, wife of a local magnate, whose amorous overtures he repulses. During a temporary absence on account of ill-health he is cheated out of his appointment. His closest friend is estranged through HELLMANN'S failure to satisfy wholly unreasonable demands upon his skill and the death of his own child from diphtheria is regarded by his neighbours as evidence of his incompetence. We are introduced to cranks of all kinds except, curiously enough, the antivaccinationist who does not appear to flourish in all parts of Germany. Against the various evil influences which oppress him HELLMANN makes little headway and it is not surprising to find him describing himself "as a slave of that many-headed monster" the public or regarding the establishment of a species of trade union as the only hope for the future of the medical profession. How many medical men in this country, with provocations hardly less real though not so sensationally accumulated as are the imaginary troubles of Dr. HELLMANN, have come to the same conclusion. We cannot support the view wholly, because the trade union implies in its aims and workings methods which are not consonant with the position of a learned profession; but we welcome the signs, which have recently become more evident, that medical men in this country are awaking to the need of organisation against abuses. A perusal of "Aerzte" cannot fail to confirm the reader in the opinion that this need is a real one.

The Fees of Public Vaccinators.

AT a recent meeting of the Surbiton board of guardians a letter was read, which had been received from the Local Government Board, approving certain surcharges made by the district auditor relating to fees paid to public vaccinators. The fees which have been improperly paid fall under two heads. A sum of more than £400 has been overpaid to public vaccinators for the revaccination of persons at places other than their own homes and a small amount has been paid for the revaccination of children less than ten years of age. The letter of the Local Government Board, to which body the question has been referred upon the refusal of the district auditor to pass the items under discussion in auditing the accounts of the Surbiton board of guardians, is as follows: "It appears that of the sums in question £453 1*s.* represents so much of the fees paid to public vaccinators for the revaccination of persons at places other than their own homes as exceeded the amounts payable under the vaccination contracts. The remaining sum of £2 10*s.* represents fees paid for the revaccination of children under ten years of age notwithstanding the express provision in the Vaccination Order, 1898, that no fee shall be paid for such vaccinations." With regard to the first item the Vaccination Order referred to in the letter of the Local Government Board lays down that vaccinations and revaccinations performed at the patient's home are to be paid for at not less than 5*s.* apiece, while vaccinations performed at the vaccinator's surgery or elsewhere are to be paid for at not less than 2*s.* 6*d.* apiece. That is to say, the rules fix the minimum sum which is to be paid in each instance, and suggest that a smaller amount should be paid when the patient comes to the vaccinator than when the medical man has to go to the patient's home. A form of contract to be used by boards of guardians and public vaccinators is appended to the rules and calls attention to the distinction between the two classes of fees by dealing with them separately. This form is presumably followed in all cases and the amounts to be paid are thus fixed beforehand by a contract which binds both parties. With regard to the revaccination of children under ten years of age, it may reasonably be contended that all successful vaccinations should be recognised as being for the public protection and should be paid for accordingly, but apart from such an argument the rule says clearly that "no payment shall be made in respect of the revaccination of any person who shall be less than ten years old or who shall have been previously revaccinated within a period of ten years." Moreover, the contracts of public vaccinators, if they follow the prescribed form, call attention to the point. The matter is one of considerable importance to medical men who are public vaccinators and who during an outbreak of small-pox may have a large amount of work thrust upon them with little time in which to discriminate and to consider the conditions under which they work. In the case at Surbiton sums ranging from a few shillings to over £100 will now have to be refunded by those who have received them in good faith, believing themselves to be entitled to them and trusting to the knowledge of the officials paying them. The latter should no doubt be sufficiently aware of the rules governing the work of the public vaccinators not to make payments which will be disallowed but this will be no consolation to those who have to endure the worry and irritation inseparable from such proceedings and who will be expected to repay money possibly at an inconvenient time. Others in their position can, however, take warning and protect themselves by carefully observing the regulations that govern the appointments which they hold and their contracts with the boards that employ them.

Annotations.

"Ne quid nimis."

IS THE DELAY IN INTRODUCING MEASURES FOR THE BETTER CONTROL OF OUR FOOD-SUPPLIES JUSTIFIABLE?

To this question we may as well reply at once and emphatically in the negative. It is now more than three years since the Departmental Committee on Preservatives and Colouring Matters issued its report. The report was published early in 1901 and one of the most important recommendations in it was the formation of a court of reference to which all food questions should be referred, and it was further recommended that no preservatives should be allowed in milk and only small specified quantities of boron preservatives in cream, butter, and margarine. Up to the present time no legislation has been made on these recommendations. Why is there so much time wasted in making statutory these recommendations, which were everywhere regarded as a source of protection to the consumer and as fair and reasonable? Again, the Royal Commission on Arsenical Poisoning issued its report on Nov. 6th, 1903, and recommended that the Local Government Board should appoint a special officer who would make inquiries for the Board into the processes

intimate that no one not possessing medical knowledge could be trusted to unravel them. It seems, however, to have fallen into the mistake of attributing the invention of the word "optologist" to the "Optical Society," of which the *Review* above quoted is the "official organ" and which has hastened to disclaim the imputed merit. The poor word, indeed, seems to have no friends. It is said by Mr. Laurance to be "of Transatlantic origin" and to be "curious and ungainly" but the fact remains that it has come into regular employment by spectacle-selling quacks. We frequently see an omnibus carrying a large outside notice board covered by the advertisement of a person who describes himself as "Eye Specialist and Optologist, qualified by examination," and whose shop has "Ophthalmic Institution" in large letters over the door. In the columns of the *Times* the advocates of the new "diploma" roar like sucking doves and profess that all they require is to be subjected to fresh "limitations" by the action of the Spectacle Makers' Company. What they really wish is, of course, to be represented to the public as the possessors of knowledge which in reality they do not and cannot possess. Assuming them to be honest men, they are not only ignorant but are in the still more hopeless position of being ignorant of their ignorance. A curious assumption by the editor of the *Review* in his letter to the *Times* is that "there are only 400 oculists." What he means by an "oculist" or how he arrives at the number is not stated, but he is clearly not aware that the conditions of vision and the nature and treatment of errors of refraction form part of the ordinary medical curriculum and that every candidate for a medical qualification is as much liable to be examined about them as about any other portion of the wide circle of professional knowledge. No medical practitioner under 50 years of age has the slightest excuse for want of acquaintance with either the diseases or the functional derangements of the eye or should be in the least liable to confound one with the other.

PARALYSIS AGITANS.

Dr. T. Stuart Hart, neurologist to the Vanderbilt Clinic, has contributed to the *Journal of Nervous and Mental Disease* for March a valuable paper on Paralysis Agitans based on the cases examined and records made in the neurological clinic of Professor Allen Starr of New York since the year 1888. The number of cases examined, amounting to 219, exceeds very much any similar series published by any one writer and as such has a statistical value which may help, adds Dr. Hart, to elucidate some facts in the etiology and pathology of this obscure disease. The majority of the patients were drawn from the humbler walks of life and advanced paralytic cases of the disease were practically excluded, as only patients who could walk were able to attend. Paralysis agitans was found to be nearly twice as frequent among men as among women, the proportion being 139 males to 89 females, or 7 to 4. The disease rarely made its appearance before the thirtieth year. In the largest proportion of cases the age of onset was between 40 and 60 years. Thus there were two cases under 30 years age, 19 cases between 30 and 40, 54 cases between 40 d 50, 88 cases between 50 and 60, 42 cases between 0 and 70, and nine cases over 70, the ages of the maining five cases being unrecorded. "Paralysis agitans, therefore, belongs not strictly to old age but rather to the presenile degenerative period." As far as could be determined occupation seemed to have no bearing on the etiology. Direct hereditary transmission could rarely be traced (16 per cent. of cases), though other neuroses were present in the ancestry in a larger proportion (about 25 to 30 per cent.) of cases. Borgherini has, however, reported a family in which of nine children three brothers and four sisters, and three children of these, suffered from paralysis agitans. Among the etiological factors assigned by the patients themselves two stood out prominently—viz., emotion (anxiety, grief, severe fright, or shock) and traumatism. "Traumatism often involved," adds Dr. Hart, "an emotional shock and it was possible that emotion might be the more important factor in many of these cases." Sudden and continued exposure and prolonged fatigue were also among the alleged causes. In 12 of the cases an acute infectious fever (typhoid fever, influenza, pneumonia, malaria) preceded the onset of paralysis agitans. It is clear, says Dr. Hart, that we are far from solving the real etiology of the disease though it is noteworthy that all the factors mentioned have in common a general weakening influence on the nervous system and the vaso-motor apparatus. Of the individual symptoms tremor was the first noticed by most of the patients (203 out of 207 in which a record was made of this). The tremor began usually in one or both hands or less frequently in the arms (163 out of 213 recorded cases), but in a few cases (one-seventh of the 163 cases) the lower limbs (foot and leg) or head were first affected and in five cases the tremors were general. Rigidity was observed in 142 cases; in 138 of these tremor was also present Tremor had existed for periods of from eight to ten years in several cases before the onset of rigidity. Contractures were noted in 28 cases; tendency to fall forward, backward, or rarely sideways during walking was noted in 63 out of 173 cases specially examined. The voice was monotonous in 59, slow and measured in 31, piping in 12, feeble in 15, and "thick" in ten out of 120 cases. Pain in the hands and arms, legs, head, and back of a dull character was present in 70 out of 157 cases and paræsthesia of the extremities occurred in 120. Hyperidrosis was complained of in 57 instances and restlessness was a marked feature in the course of the disease in 85 cases. The treatment of the cases followed well-known lines and included rest from work, removal of sources of worry and anxiety, abstinence from alcohol and stimulants, a simple nutritious diet, moderate exercise, passive movements, massage, and hydrotherapy, and such drugs as hydrobromate of hyoscine and sulphate of duboisine which diminished tremor and pain. Improvement followed in a few cases, the disease coming to a standstill and remaining so for a number of years, with relief of tremor, pain, and insomnia, but, adds Dr Hart, no absolute cures could be reported.

THE DISTRIBUTION OF PLAGUE.

THE public health authorities of New South Wales inform us that after an immunity of nearly seven months during which Sydney was free from plague infection a mouse was ascertained to be plague infected on March 7th. The mouse came from a building known as the Grafton Bond at Darling harbour. The rat-catching staff of the board of health has been instructed to pay particular attention to the wharves and bonds between the gas company's works and Erskine-street, within which locality the Grafton Bond is situated. Since the mouse was captured (about one week before a definite diagnosis was made) 250 other rodents have been caught within the area above mentioned but all were free from plague. During the last outbreak of plague in 1903 there were 161 plague infected rats and mice caught but only 2 cases of the disease occurred in human beings. It is hoped that the vigorous measures now being taken with regard to rodents will have as good an effect in limiting the outbreak of this year as was the case in 1903 Plague has also appeared in Queensland, as reported in our correspondent's letter at p. 1088. In the Cape Colony for the week ending March 19th only 1 case of plague was discovered in human beings—namely, that of a coloured female at Port Elizabeth. Plague-infected rodents were found there and at East London, but in the Cape Town and

Harbour Board area of 375 rats examined during the week none was affected with plague. As regards the Mauritius, a telegram from the Acting Governor received at the Colonial Office on April 8th states that for the week ending April 7th there were 3 deaths from plague. The latest returns from the Transvaal show the following figures, as contained in a telegram from Lord Milner received at the Colonial Office on April 9th:—Suspected cases reported up to date, 154: coloured persons, 136; and whites, 18. Deaths, 72: coloured persons, 65; and whites, 7.

THE QUESTION OF HEREDITARY TRANSMISSION OF ACQUIRED MORBID CONDITIONS FROM PARENT TO OFFSPRING.

IN a recent *Thèse de Paris* (1904) Dr. G. Delamare of Paris, working at the laboratory of Professor Charrin, has given an account of the results obtained by him in this branch of study. Hereditary transmission from the parent to the embryo, says Dr. Delamare, may take place in one of three ways: first, the germ-cell or the ovum may be damaged or altered as the result of grave constitutional disturbance or disease acquired by the mother at or before the time of conception, a similar condition being possible also as regards the spermatozoa of the male parent; secondly, the impregnated ovum before it has undergone differentiation into it embryonic rudiments (pre-embryonic stage) and while still free in the Fallopian tube or encapsuled in the uterus may be subject to the action of toxic, cytolytic, and other disturbing morbid agencies present in the maternal blood plasma; and, thirdly, the embryo may be affected *viâ* its placental attachment to the mother which takes place at the third week and marks the beginning of embryonic life proper. These modes of hereditary transmission are not identical and should not be indiscriminately confounded under the general term "heredity." By "acquired" characters in the pathological sense are to be included, says Dr. Delamare, those changes of a physico-chemical or morphological nature which are produced *de novo* within the parent organism, not having been inherited by it *ab ovo* but caused by the action of extraneous agencies of sufficient potency. Thus insanity or gigantism may appear in a man or woman whose parents are free from either of these affections and the man or woman thus affected may transmit the morbid condition in question to the offspring in a very marked degree. The same applies to cretinism. Gout of the father will, says Dr. Delamare, predispose to gout in the son whom he procreates and so will tuberculosis of the father predispose to a vulnerability or facile tendency of the son to acquire tuberculosis. Leucocytes are found to be able to transmit to their descendants (daughter leucocytes) the power of immunity acquired against certain diseases (Massart). That superficial and slight mutilations of the parent, such as circumcision and the rupture of the hymen, are not inherited is due to the fact that these do not produce bodily disturbance of nutrition or affect the composition of the blood and therefore cannot affect the germ or sperm cells. No nexus of cause and effect exists, but as the consequence of serious lesions of the nervous system or viscera of the parent experimentally produced Dr. Delamare states that the offspring may show in the corresponding organs conditions of disease or abnormality the nexus of which can be traceable as effect and cause. Thus as regards serious lesions of the central nervous system attended with constitutional disturbance the classical experiments of Brown-Séquard on guinea-pigs have shown that a special form of epileptic attack accompanied by certain trophic lesions, produced by hemisection of the dorsal spinal cord (rarely of the cervical and never of the lumbar spinal cord), is transmitted to the offspring with great frequency. These experiments have been confirmed by Obersteiner, Westphal, Dupuy, and Romanes, and by Dr. Delamare himself. A similar form of epilepsy produced in guinea-pigs by a less serious lesion—viz., section, crushing, or laceration of the great sciatic nerve—is also hereditarily transmissible. Massin excised half the liver in buck and doe rabbits and found that the descendants had small and malformed livers. Dr. Delamare found that removal of a kidney or of one suprarenal body in several guinea-pigs did not affect the corresponding organs of the offspring. Experiments were also made on two bitches, three rabbits, and 17 guinea-pigs to bring about local destruction of parts of the liver (hepatitis and localised cirrhosis) by injections of naphthol, distilled water, and dilute solutions of silver nitrate, all with positive results (partial atrophy, cirrhosis, and maldevelopment of the liver) as regards the offspring of these affected animals. He states that cytotoxins and cytolysins are liberated from the affected organ and circulate freely in the blood, and that such cytotoxins influence the germ cell or developing ovum while still in the embryonic state, causing it to develop and to manifest the characteristic lesions of the liver while still in utero. It was also found that hens which were hypodermically injected with extracts of such cytolysins laid eggs which were abnormal and damaged, inasmuch as when hatched they showed an unusual proportion of malformed embryos, dead embryos, amniotic hæmorrhages, and other abnormalities. Of 27 eggs of hens thus treated 21 showed the abnormal characters in question. The injection of bitches with hepatotoxins and nephrotoxins also produced lesions of the liver and the kidney in the growing embryos in utero. Dr. Delamare thus concludes that there are modes of hereditary transmission to the offspring of diseases and tendencies to disease (diatheses) from parents who have acquired them and that in some cases the pathological nexus of cause and effect can be traced.

THE WINTER'S WEATHER AT SOME ENGLISH RESORTS.

THE following table gives a summary of the temperature, rainfall, and bright sunshine for the whole of the winter—Dec. 1st to March 31st—at several of the chief resorts in these islands. Similar statistics were published in THE LANCET of March 12th for the three months, December to February, at seven of the principal resorts abroad. As would naturally be expected the majority of the latter were warmer than the home stations, but there were, nevertheless, two or three notable exceptions. The winter at the

Stations.	Temperature.						Rainfall.		Sunshine
	Highest maximum.	Lowest minimum.	Mean maximum.	Mean minimum.	Mean of maximum and minimum.	Difference from average.	No. of days with rain.	Total fall.	Total number of hours.
	Deg. F.	Deg. F.	Deg. F.	Deg. F.	Deg. F.	Deg. F.		Ins.	
Harrogate	56	20	41	34	37·5	–0·7	79	11·3	193
Bath... ...	59	21	46	35	40·5	–1·0	72	10·8	196
Tunbridge Wells*...	57	23	43	33	38·0	–1·5	57	10·8	155
Hastings...	55	23	43	33	38·0	–2·4	80	11·0	222
Torquay ...	59	30	47	39	43·0	–0·2	78	18·7	265
Falmouth	55	30	47	40	43·5	–0·6	83	24·0	254
Scilly Isles	55	33	49	42	45·5	–0 6	88	18 7	260
Jersey ...	56	28	47	39	43·0	–0 6	85	14·9	285

* The observations for Tunbridge Wells are for January to March only.

Scilly Isles, which represents fairly well the weather in the Penzance district, had about the same average temperature as Nice and Florence, while as regards the average temperature of the night Scilly was superior to both the Italian and the *Rivieran resorts*, while in Torquay and Falmouth the nights were just as warm as those at Nice. At most of the English stations, too, the difference between the day and night temperature showed less range than some of those abroad. Nice, for instance, had a mean diurnal range of 13°, but at the Scilly Isles and Falmouth, as well as at Harrogate, the range was no more than 7°, while at Torquay and Jersey it was only 8°. During the three months, December to February, the screened thermometer fell to 32° or below on 11 nights at Biarritz, on six at Florence, on three at Nice, and on one occasion even at Rome. But Scilly was entirely without frost throughout the winter, the screened instrument only once descending to near the freezing point, and at Torquay and Falmouth there were only two or three slight frosts. The aggregate rainfall at the home stations was less than at some of those abroad although it had a month longer in which to fall. The number of days with rain are not strictly comparable, as a "day with rain" at the foreign stations signifies a day when at least four-hundredths of an inch of rain has fallen, while with us it means a day when at least one-hundredth of an inch has fallen. It is a pity that all the stations do not give the percentage of ozone present in the atmosphere; at Torquay, where the borough meteorologist takes careful observations, the percentage of the possible amount for the whole winter was 47. It was least—38—in December and greatest—59—in February.

A CASE OF TUBERCULOUS DEPOSIT IN THE SPINAL CORD IN THE COURSE OF PULMONARY TUBERCULOSIS.

Dr. Ernst Oberndörfer of Berlin records in the *Münchener Medicinische Wochenschrift*, No. 3, 1904, a case of considerable interest from the Moabite Hospital at Berlin under the care of Professor Goldscheider. The patient was a man, 26 years of age, who had for some time suffered from tuberculosis of the lungs. He began to complain of disturbances of the act of defecation and difficulty in emptying the bladder, with wandering pains in the epigastric and lumbar regions. Later a paresis of the left leg developed with some impairment of sensation of the lower half of the body. The condition was regarded as one of compression paraplegia and weight extension was applied; in spite of this the condition of the patient became rapidly worse, complete paraplegia with retention of urine developing. Meanwhile the pulmonary disease advanced rapidly and six weeks after admission to the hospital the patient died. Before death the original diagnosis of compression paraplegia was discarded and the correct one of tuberculosis of the spinal cord was made on the following grounds—the co-existence of the lung condition, the absence of the objective signs of vertebral caries, and the manner of spread of the cord symptoms beginning with unilateral paralysis and local patches of anæsthesia and gradually advancing to complete paralysis and loss of sensation. The necropsy confirmed the diagnosis: the vertebræ and meninges were natural but in the lower dorsal region of the cord a bean-shaped swelling was found projecting slightly above the surface on the posterior aspect. A cross section was made at the level of the eighth thoracic segment, when a yellowish white tumour, sharply marked off from the softened cord tissue around, was exposed. Its internal border was surrounded by a narrow zone of greyish red translucent tissue. The tumour occupied the whole of the left side and extended into the right side of the cord at this level, leaving only a small area of the white matter of the antero-lateral region unaffected. It extended downwards in conical form and ended at the ninth thoracic segment. A piece of the tumour examined microscopically showed a mass of conglomerate tubercle, caseous centrally, and surrounded by fresh nodules in which typical giant cells were found and abundant tubercle bacilli. Apart from the rarity of this condition, of which Herter reported three cases, collecting records of 24 others from the literature of the subject, this case is of interest from the correct diagnosis having been formed during life and from the admirable and instructive way in which it is recorded.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

OUR readers will remember that the Prince of Wales, the President of King Edward's Hospital Fund for London, announced at a meeting of the general council of the Fund held at Marlborough House on March 8th that a large sum of money, estimated to produce £4600 a year, had been promised by a friend if a further sum of double that amount were obtained by the end of the year. The object of the anonymous donor is to enable the council to make its distributions to hospitals without drawing upon its reserves as it had to do last year when a sum of over £18,000 was thus appropriated to complete the grants. Towards this object a donation of £1000 has been received by the Fund from "G. W. O." and a legacy of £10,000 from Mr. F. S. Massy Dawson, the executor of the late Mr. Richard Hawkins Beauchamp. Mr Hugh C. Smith, the chairman of the executive committee, has issued an appeal for further donations towards making up the sum required and he announces that he will be glad to give any further information concerning the Fund. The address of the Fund is 81, Cheapside, London, E.C.

THE EARLY DIAGNOSIS OF PERFORATION IN TYPHOID FEVER.

MORE than a fourth of the deaths from typhoid fever are due to perforation. The value of operation has been abundantly shown in recent years. At the Johns Hopkins Hospital six patients have been saved out of 14 operated on. Dr H. W. G. Mackenzie has published an eminently practical paper in the *Practitioner* for January in which he points out that as good results may be obtained in general as in hospital practice if the practitioner is on the alert to give the patient the benefit of prompt operation. He very clearly states the points in the early diagnosis of perforation. The danger of perforation commences with the disease and lasts until recovery is complete. Perforation may occur before the patient feels ill enough to take to bed or during convalescence. The greatest risk is during the second, third, and fourth weeks Abdominal pain is the most important early symptom and may be the only one. It usually comes on suddenly and is severe and persistent. Vomiting, nausea, hiccough, frequent actions of the bowels, a rigor, sweating mental excitement, or collapse may precede, accompany, or quickly follow the onset of the pain. The nurse should be instructed to report at once to the practitioner the occurrence of pain or any other of these symptoms When summoned the medical attendant should carefully examine the patient for the following signs of perforation. 1. There may be a change in the temperature—a sudden fall or a sudden rise, or a fall followed by a rise, or a rise followed by a fall; but a steady temperature for a few hours does not negative perforation. 2. There may be a change in the pulse; soon after perforation the pulse usually becomes more frequent and weaker. It is highly significant if the pulse in the few hours following the attack of pain becomes more rapid, running, and feeble; but increased rapidity does not invariably follow within a few hours. 3. There may be a change in the facies. The development of a pinched or drawn look, depression of the angles of the mouth, sinking in of the eyes, blueness of the lips, and sweating are important. 4. Still more important are the local abdominal signs. There may be tenderness which usually is more marked in the lower half of the abdomen. Rigidity or resistance of the abdominal walls may be present. The abdomen may be retracted or distended but in either case there will probably be rigidity or resistance. On the other hand, softness or flaccidity is reassuring. Obliteration of liver dulness is a valuable sign if present but is not free from ambiguity; it is confirmatory of the diagnosis of perforation of a hollow viscus. Shifting dulness in the flanks may point to the presence of free fluid in the peritoneal cavity. Finally, there may be diminished respiratory movement of the abdominal wall. Dr. Mackenzie advises that the practitioner should select the surgeon beforehand, so as to obtain him equipped in the shortest possible time.

A FESTIVAL dinner in aid of the funds of the Middlesex Hospital will be held on Tuesday, May 3rd next, at 7.30 P.M., in the Whitehall Rooms of the Hôtel Métropole. The Right Hon. the Lord Mayor will take the chair. A preliminary list of gentlemen who have consented to act as stewards has been issued and contains 192 well-known names. Noblemen and gentlemen willing to act as stewards are requested kindly to send their names to the secretary-superintendent of the hospital, Mr. F. Clare Melhado. The chairman of the dinner committee is Lord Sandhurst and the deputy chairman Prince Francis of Teck. The dinner will be free of charge and contributions are earnestly solicited. It is stated that the proceeds of the dinner will be devoted to the purposes of making good the inroads on invested capital which have been necessitated by new buildings and other improvements to meet the demand of modern requirements and for the maintenance of the cancer charity and the special department for research into the nature and cure of cancer, the hospital's branch establishment for convalescents at Clacton-on-Sea, and improved and extended accommodation for the nurses.

A GENERAL meeting of the Metropolitan Street Ambulance Association will be held at 20, Hanover-square, London, W., on Monday, May 2nd, at 5 o'clock. Important motions will be submitted for consideration, amongst them one in favour of sending a representative deputation to the London County Council early in May. All medical men are invited to attend. 1000 London medical men have already joined the association. The fact that membership incurs no liability and that there is no compulsory subscription necessitates the formation of a fund to provide for printing and incidental expenses. Members wishing to contribute small donations of a few shillings are invited to communicate with Dr. Arthur W. James, honorary secretary, at 69, Gloucester-terrace, Hyde Park, W.

THE death of Sir Philip Crampton Smyly took place at an early hour on Friday, April 8th, at his residence, 4, Merrion-square, Dublin. He had suffered from gout for a long period but in the end his death came unexpectedly, for after dinner on Thursday he complained of illness and died at two o'clock on the next morning. He was for many years one of the best known and most eminent of Dublin surgeons and on account of his high social qualities and invariable courtesy was greatly esteemed. He was President of the Royal College of Surgeons in Ireland in 1878, representative of the College on the General Medical Council from 1895 to 1900, President of the Irish Medical Association 1901 to 1902, in 1895 was appointed Surgeon-in-Ordinary to Her Majesty Queen Victoria in Ireland, and in 1901 Honorary Surgeon to His Majesty the King. We shall publish a fuller obituary notice.

THE Ingleby Lectures of the University of Birmingham for 1904 will be delivered on Tuesdays, May 10th and 17th, at 4 P.M., in the medical lecture theatre, by Dr. C. J. Cullingworth, obstetric physician to St. Thomas's Hospital, who has taken for his subject, a Plea for Exploration in Suspected Malignant Disease of the Ovary.

THE FIRST INTERNATIONAL CONGRESS OF SCHOOL HYGIENE.

(FROM OUR SPECIAL CORRESPONDENT.)

THE First International Congress of School Hygiene was held from April 4th to 9th at Nuremberg under the patronage of His Royal Highness Prince Ludwig Ferdinand of Bavaria

It may be well to state, first, the object of the Congress and, secondly, by what bodies the English and foreign interests were represented. The object of the Congress may shortly be said to be to direct the attention of existing authorities to the importance of, and the practical means of attaining the most perfect results in, the physical and mental wellbeing of children, to direct attention to the hygiene of the teachers themselves, and, lastly, to give an opportunity to those especially interested in the wellbeing of the young to study and to appreciate the means whereby this object can best be attained.

The English interests at the Congress were represented by a special committee formed by members of various organisations interested in education and school hygiene. The formation of this committee was due to the energy of the medical officer to the London School Board, Dr. James Kerr. The English committee includes representatives of the following bodies: the Royal College of Physicians of London, the Royal College of Surgeons of England, the London School Board, the Medical Officers of Schools Association, the Incorporate Society of Medical Officers of Health, the London School of Medicine for Women, the Childhood Society, the Child-Study Association, the National Union of Teachers, and the Sanitary Institute, and was under the presidency of Sir Lauder Brunton.

The first general meeting of the Congress took place in the Apollo Theatre, Nuremberg, on April 5th and was attended by nearly 1500 members. The chair was taken by Professor Dr. GRIESBACH, the President of the Allgemeiner Deutscher Verein für Schulgesundheitspflege, and he requested Prince Ludwig Ferdinand to open the Congress.

Prince LUDWIG FERDINAND said that it was with the greatest pleasure that he had come to open the First International Congress of School Hygiene. It was the ancient and historical town of Nuremberg which opened its doors to the Congress. This was the town in which such masters as Albrecht Durer and Hans Sachs had lived and by their art and genius had added to its fame. He welcomed the delegates from distant States and countries and said that they had come together for the purpose of discussing the means for developing the coming generation into healthy and educated men and women. He wished the Congress success in its work and declared the First International Congress of School Hygiene open.

Professor Dr. GRIESBACH welcomed the delegates from the various countries and from the numerous societies. He said that no less than 20 European and extra-European States were represented at the Congress and that only Turkey and Italy were unrepresented. It had unfortunately been impossible to form an Italian committee. It was in such work as the Congress had before it that the medical man and the teacher must work hand in hand. The delegates from the various countries then spoke, Dr. A. EICHHOLZ, His Majesty's inspector of schools for the blind, deaf, and defective, replying on behalf of Great Britain.

At the closure of the formal business of the meeting the first general meeting of the Congress was held and Professor COHN (Breslau) read a paper entitled "What has the Ophthalmic Surgeon done for School Hygiene and what remains

to be done?" More than 40 years ago he had inspected the schools in Breslau and it had been his first duty to see that the schools were better lighted. In those days there was neither school hygiene nor school medical officer. The well-known work of Helmholtz, Graefe, Arlt, and Donders had, indeed, appeared but had not been applied to the hygiene of schools. From 1864 to 1886 the speaker had examined the eyes of 10,000 school children and was in search of the cause of the increasing short sight and of a means of preventing this defect. This work was the starting point of work on school and eye hygiene the literature of which had now become so vast that it was no longer possible to examine it all. He found, in the first place, that the number of short-sighted children steadily increased with the development of the school from the lowest village school to the gymnasium; in the second place, that the number of cases of myopia increased from class to class; and in the third place, that the degree of short sight also increased from class to class. These facts had now been proved by examination of thousands of children in various lands and might be stated as "laws." Myopia might be regarded as a widespread disease produced by school life. Further experience in the last ten years had shown that the acuity of vision in young children examined in the country was twice or three times as great as that of a child examined in the school room—similar to the great acuity of vision which was present in the Bedouin Arab. Unfortunately the acuity of vision diminished during the years of school life very rapidly. The true cause of short sight—viz, the change in the shape of the eye from a ball to that of an egg—was not even yet fully known, although there were various hypotheses. One thing was certain—that much close work, especially in association with hereditary disposition and bad lighting, produced myopia and that school hygiene must more especially fight against such near work. 20 years ago Professor Stilling had attributed the short sight not to work but to an alteration in the shape of the orbit. This view could not be upheld on anatomical grounds and it was greatly to be regretted, since if such were the case it would render all the work in connexion with school useless in the prevention of myopia. The position of the writing table and the position in which the pen was held were important and it had been shown that less short sight resulted when these points were carefully considered. The character of the print of books was an important matter and the speaker regretted that even at the present time in Bavaria books were allowed which were badly printed. Professor Cohn next dealt with the lighting of the rooms. In 1883 he had first used the photometer of Weber and had been able accurately to estimate the light of the schoolroom. A definite unit of the minimum light allowed was established and he had found in a gymnasium in Breslau only a tenth of the minimum light was present in some places. In the same school he found that the greater number of the children could not see the sky. He then showed various methods for estimating the light in a room and at a given point in the room. He had for many
years advocated the appointment [illegible]
examination of school children.
medical officer was appointed to
in Germany there were but 676
much had been done yet the number of short sighted students had not diminished. He had in 1867, in 1881, and again in 1902 found 60 per cent. of short-sighted students in Breslau. Further attention must be paid to the lighting of the school rooms and to the position in which the child held the head whilst at work. He next dealt with the question of the influence of heredity on the production of short sight and was of the opinion that two short-sighted people should not marry. It was of importance that the regulations imposed in school should also be maintained in the home The speaker ended his address by the words "Keine Schule ohne Augenarzt" (no school without an ophthalmologist).

Dr. Benda (Berlin) spoke on the subject of over-pressure in the more advanced classes. He recommended the abolition of the so called Abiturienten-Examen (the final examination which entitles young men to matriculate as students at the universities). No lessons should be given in the afternoons, so that the children might have ample opportunity for bodily exercises and games. Home lessons ought to be limited as much as possible. Special classes for defective or backward children ought to be arranged in the gymnasia,
as was already the case in the
advanced pupils ought to be
they wished to attend with a
or position in life. In this way the change from the restraints of school training to the wider circle of university studies would become less abrupt than under the present system.

Dr. Schmidt (Bonn) recommended that bath rooms should be provided in schools and that douche baths should be obtainable. Swimming ought to be made compulsory for children above ten years of age.

Dr. Gutzmann (Berlin) read a report on Stuttering and Stammering Children. He had observed that stuttering was comparatively frequent during the first years of school life and during the period of puberty. By a collective investigation made on 3000 pupils it was ascertained that of each 100 stutterers 6 per cent. were aged from six to seven years, 10 per cent. from seven to eight years, and 15 per cent. from 11 to 12 years. He was of opinion that over-pressure, especially in neuropathic children, contributed to the development of stuttering. On the other hand, he believed that stammering diminished as a result of school training, so that of each 100 stammerers 29 were found to be aged from seven to eight years and only 6 per cent. were from 13 to 14 years.

Dr. Grevo (Munich) discussed the influence of diseases of the teeth on the mental development of children. He said that a great many children in the municipal schools suffered from caries of the teeth. These children were as a rule badly nourished because they were unable to digest satisfactorily and their mental capacity was defective in consequence of this. Regular inspections of the teeth of the children should be provided for in the regulations made by school authorities.

Professor Schusny (Budapest) read a paper on Sexual Questions in Relation to School Life. He recommended that children previously to the age of puberty should be informed on sexual matters by their parents and that teachers of natural science should on suitable occasions allude to these questions. In the Hungarian schools, where lessons on hygiene were given, these requirements were already met. He said that for the last ten years he had been in the habit of delivering addresses to youths who were leaving school, advising them on sexual hygiene, on the danger of venereal diseases, and on the advantages of chastity.

An address was delivered by Professor Axel Van Johannessen (Christiania) on the Position of School Hygiene in Norway. He dealt in the first place with the developments of the school, and stated that since 1889 the schools in the country had greatly improved. He said that not only on the boys but also on the girls gymnastics were obligatory. There was a medical officer in every school and warm baths were provided in most of the schools in Christiania. In the towns, also, many of the poorer children were fed and this cost the State about 160,000 kronen a year. The elder children had games of which the most important was "ski-ing." The upper classes were taught physiology and the teachers were taught school hygiene

Dr. Le Gendre of Paris delivered an address entitled "Sur l'hygiène et les maladies personnelles des maitres au point de vue de leurs rapports avec les élèves."

The second general meeting was held on April 7th. The first paper by Dr. Phil. Seckenger (Mannheim) dealt with the arrangement of schools dependent on the mental capacity of the children. He said that the capacity of children for education depended on physiological, psychological, pathological, and social circumstances and that it was impossible to order the education of all children on one set plan, but that the children must be regarded as individuals of different capacity He divided the school children into three great groups: those with good capacity, those with less than the normal capacity, and those with but little capacity (weak minded), and on educational, ethical, and social grounds provision should be made for these three classes. He then described such a system which was in operation at Mannheim.

At the last general meeting of the Congress Dr. James Kerr read a paper entitled "What is Most Required in School Ventilation." He said there was required for all schools some efficient method of ventilation. In small rooms this might be a modified natural system, by fires or ventilating stoves. Other systems depending on roof ventilators and climatic conditions were fallacious and whilst acting during some seasons of the year failed in summer, and caused draughts in winter. Open windows, doors, and fireplaces, or extraction chimneys could, by a rigorous system of window-drills and the constant supervision of a skilled teacher, be utilised for most of the school year to maintain a comparatively pure air, but even these methods would fail when most wanted, as in summer. For large schools direct mechanical movement of the air was best by large fans running at low speeds. In order to avoid "short-circuiting" by opening of doors all ducts should be as large as could be afforded and the outlets of low resistance; inlets to rooms should be high on the walls, outlets low; 2000 cubic feet per head per hour should be supplied. Accessory heating preferably by low pressure steam or water was advisable. The air should be well moistened. Cloakrooms and stairways must also be ventilated. At present the chief objection to the mechanical ventilation was the sense of loss of tone from want of sufficient skin stimulation by the smoothly flowing warmed air. Probably the system of the future would be one of large supplies of very moderately heated air moved by combined propulsion and extraction by fans, with accessory heating of rooms and free permission to open doors and windows.

The Exhibition.

The exhibition was conveniently held in the same building in which the sectional meetings of the Congress were held, the upper and lower floors being devoted to this purpose. *A considerable portion of the exhibition was devoted to* the architectural drawing of schools. Most of the plans show an elevation of three floors; on the one side there is a corridor, out of which the various class rooms open, and the same arrangement is repeated on each floor. In the basement provision is made for a bath which may be a swimming bath or more usually a shower bath. A gymnasium is always provided and is in most plans arranged as a building separate from the main block. The variety in the arrangements of the buildings is considerable but all plans provide for the gymnasium and for a bath in some form. A large portion of the exhibition was occupied by school desks in various forms; the general arrangements seemed to be to make the desk and seat to accommodate two children and various devices had been adopted to allow the children to stand up in their places and yet to bring the desk sufficiently near them to prevent them stooping over their work. This arrangement differs from that adopted in the English schools in that the desk is made continuous while the seats are separated for each child. Such an arrangement allows the teacher to pass behind the children and to give to each child room to stand up at the side of his place, whereas in the arrangement shown in the exhibition the teacher is at the side of the scholar and cannot pass behind him. Various mechanical arrangements were shown for adjusting the desk and seats to the varying size of the children, but of these, all more or less complicated, no mention need be made. Generally speaking, it may be said that the desks appear heavy and in most instances to have an excess of ledges for the accumulation of dust. One form of drawing stool may be especially mentioned as it is both ingenious in design and most comfortable to work at. It is shaped as a somewhat flattened horseshoe on four legs. At one end a pillar is fixed which carries a drawing board which can be adjusted at any angle and at any height. From the same pillar an arm projects which carries a stand on which the object to be drawn is placed. The student, male or female, sits on the other end of the horseshoe with the legs in the concavity, or if the student be a male he can sit on the stool in a straddle manner. The only objection that can be raised to such a stool is the fact that it occupies a considerable amount of floor space as compared with a chair, but in comparison to an easel it occupies but a small space.

The above may be said to be the main features of the exhibition. Mention, however, may be made of a simple form of hygrometer for school use. The advantage of knowing the amount of moisture in the atmosphere of the schoolroom is obvious and means can be taken to correct the defect. Some of the diagrams for instruction appear to be worthy of note and one showing the joints cut from a bullock would seem to be of considerable use in the education of girls in housekeeping. Some of the models illustrating the anatomy of the human frame would appear unnecessarily complicated for such simple facts as are required in the education of children. The typewriting machine as used by the blind is of interest. It in some way resembles the Brail system, but by the various combinations of six keys any letter can be made and the word is stamped out and can be read either by the blind person or by sight. The disadvantage of the process is its extreme slowness, for the formation of nearly every letter requires the keys to be depressed three times. Various models for the artificial lighting of rooms were shown. That which seemed the most in favour was the method by which the light was thrown on to the ceiling and only an indirect and diffuse light was thrown on to the book or drawing. Samples of clay modeling, of drawing, of painting, and needlework were shown but called for no special notice. As a whole, it may be said that the exhibition showed but little that was new.

The Primary Schools.

A visit to one of the primary schools gives possibly a better idea of the arrangement of these buildings than a study of many drawings. The school visited was a building of recent date; it was a three-storey building arranged in the shape of an E. The upper half of the E was for girls while the lower half was for boys. The middle stroke of the E was a gymnasium and was a single storey building. This could be used either by the boys or the girls. Behind the E was a playground. One long corridor ran along the inner side of the E and out of this corridor opened the various rooms. The corridor was divided by a door on the lower two floors so as to separate the boys and girls. The class rooms were made to accommodate about 60 children and the *desks were arranged in three rows, the seats being in pairs.* For cleaning the floor, which was covered with linoleum, the desks and seats tilted up in a lateral direction so that it was possible to clean completely the floor surface. Arrangements were made for the children's hats, coats, and umbrellas in the class rooms. The class rooms were arranged for Roman Catholic and Protestant instruction and also for "simultan" or mixed instruction. On the girls' side one room was fitted as a kitchen, four small stoves being provided and four tables.

Leading out of the corridor on the ground floor was the gymnasium which was well fitted and arranged and could be used either by the girls or boys. In the basement was the bath room and each child has a bath once a week. The shower bath is the form used and some eight to ten children can take their bath at the same time. Warm and cold water are provided and the regulation of the temperature is in the hands of the attendant. Each child is provided with a cap for the head, a pair of bathing drawers, and a towel. In the basement can also be seen the arrangements for ventilation of the building. The fresh air enters through a coarse filter, passes up shafts into each class room, and the air is warmed by passing over hot-water pipes in the rooms. Arrangements are made by having a small hole in the wall of each room so that the attendant can tell the temperature of the room by observation of a thermometer placed against the wall, without going into the room and disturbing the class. On the third floor is a large hall which occupies a position between the girls' and boys' class rooms and is therefore available for both or either. Although the structure and arrangements of the building differed from those commonly seen in English schools yet the arrangements had much to be commended. A school differing somewhat in detail but similar in the main was also seen. This school had, however, four floors and the large hall was situated over the gymnasium, at the corner of the square, of which the school formed two sides.

THE MOSELY COMMISSION.

THE reports of the various members comprising the Mosely Educational Commission to the United States of America have just been issued and form a volume which will, we think, prove of great value to those interested in education. The book, however, demands close study and the contents are not arranged in the most convenient manner for reference. Thus there is no index and the joint report which apparently summarises the conclusions of the Commissioners is barely one and a half pages in length. There is, in addition, a series of summaries of each report but if the reader wishes to find the opinions of the Commissioners upon any single point his search is by no means made easy. These omissions will, however, we have no doubt be *rectified in a future edition* when we hope to see a really good subject index added. The idea of the Commission was started in Mr. Mosely's mind by the excellent work which he noticed to be done by American engineers in South Africa some 15 years ago. To one of these, Louis Seymour, Mr. Mosely reminds us that we owe a debt of gratitude for the admirable way in which he and his volunteer company kept open communications in Natal during the Boer War. Seymour lost his life while leading some men to cover for the defence of a bridge at Zand River. Some years before the war Mr. Mosely visited the United States to see for himself "what sort of country it was that was responsible for sending so many level-headed men to the Cape." On his return he organised two commissions, the one an industrial commission and the other an educational commission. The "terms of reference" of the latter were as follows:—

> [illegible]

Mr. Mosely pays a warm tribute to the people of the United States for the assistance which they gave to the Commission and the hospitality which was so freely proffered.

The joint report expresses the deep impression made upon the Commissioners by the evidence which they have gathered in the United States of the absolute belief in the value of education both to the community at large and to agriculture, commerce, manufactures, and the service of the State. An overwhelming desire to learn appears to characterise the scholars and teachers seem to be possessed of but one wish—that of helping their pupils in every possible way. There is a close connexion between theory and practice, the practical bent of the men of science and letters and the breadth of their outlook being very remarkable. Both the public and private donors give liberally on behalf of education, specially as regards buildings and equipment. But the remuneration of teachers is by no means always on a satisfactory basis and the members of the Commission "have also been led to view somewhat with alarm the growing preponderance of women teachers." The absence of any religious difficulty serves to facilitate the work of the schools. We notice, however, that an instruction to the Commissioners was that religious controversy in connexion with education should be absolutely ignored, so that these reports will not help us on this side of the Atlantic seeing that we are at present passing through an acute stage of the religious difficulty as regards education.

We shall not attempt to deal with the separate reports other than with those of Professor J. Rose Bradford who deals with advanced medical education and of Dr. W. H. Gaskell who deals with the teaching of anatomy and physiology. Professor Rose Bradford subdivides his report into: (1) the Relation of Hospitals to Medical Schools; (2) Clinical Laboratories; (3) the Teaching of Medicine; and (4) Pathology. The medical schools visited were, in the United States, those of New York, Philadelphia, Baltimore, Chicago, Ann Arbor, Boston, and Ithaca, and in Canada Montreal, Toronto and Quebec. The schools in [illegible] ciated with the medical departments of the universities and their clinical facilities were not exclusively employed for the instruction of the students of a single university or school. In some cities, however, as Baltimore and Montreal, one hospital is entirely devoted to the needs of a single medical school—namely, the Johns Hopkins Hospital at the former and the Royal Victoria Hospital at the latter. In a great many hospitals both in the United States and in Canada the members of the visiting staff are only on duty for a period of three or six months and at the end of this period the wards are transferred to another physician or surgeon. The system of student clerks and dressers scarcely exists in the United States except at the Johns Hopkins Hospital, though it is in full operation in Canada. In most American hospitals, however, the ward work is done by internes who correspond to house physicians and house surgeons. Professor Rose Bradford summarises the first portion of his report as follows:—

> These two points—on the one hand the limited period of service of the visiting and teaching staff and on the other the absence of the [illegible] system the students get the practical acquaintance with disease subsequently during their period of office as "internes," at a time, moreover, when they are more fully capable of making use of the opportunities afforded them. In the English system the student becomes a clerk or dresser at a period in his career when he knows little or nothing of medicine or surgery and thus they argue that the great opportunities afforded him are to a considerable extent wasted. With their system the "interne" has already graduated and has acquired a knowledge of medicine and surgery which should enable him to make full use of his opportunities. The great and obvious disadvantage of the American system is clearly the fact that [illegible] rnes" and thus a number [illegible] advantages that the daily [illegible] parts. I was informed on [illegible] students in the leading [illegible] ently to graduation either [illegible] ls or in some other city or [illegible] cent. of the students not only graduate but pass out into practice without this invaluable experience. This is a very striking, if not the most striking, difference between the system of medical education in vogue in the United States and that followed in this country and also in Canada.

As regards clinical laboratories these in most of the institutions visited were a conspicuous feature. In all the medical schools there is a tendency to bring clinical medicine more closely into relation with recent scientific developments than is the case in this country, blood counts and other investigations being made not merely from a diagnostic point of view for any particular case but in a more or less routine fashion. Such a practice must tend to put medicine on a more scientific basis. As regards the teaching of medicine the work is far more systematised than in this country and the individual student is more supervised throughout the course of his studies. Didactic lectures are almost entirely given up and in most subjects their place has been taken by a great development of laboratory work. In medicine, however, their place has been taken by what are called "recitations." A "recitation" is apparently what we should in this country call catechising—that is to say, a subject is given for treatment and the teacher questions his class upon it and is also asked questions by his class. Professor Rose Bradford seems much impressed by the value of this method. The absence of ward work for students is more or less made up for by small classes under the charge of an instructor who teaches physical signs and the taking of histories. Physical diagnosis is often studied by the student in his second year [illegible] largely made use of for [illegible]

With regard to pathology, the teaching of this subject and the buildings and requirements for teaching it seem to be far ahead of the average establishments in this country. Pathology includes morbid histology, bacteriology, gross morbid anatomy, and, in some cases, clinical pathology. The subject is as a rule begun to be studied in the student's second year. One special point about the instruction is the practice of giving unknown cultures or unknown sections to the students [illegible] record of every [illegible] demonstrators [illegible] point and the [illegible] specimens are worthy of imitation in this country.

Dr. Gaskell in his report upon the teaching of anatomy and physiology first draws attention to the fact that there are no outside examiners either in the United States or in Canada. In all cases the question whether a student passes or not is decided by his teachers and not only by a separate examination but also by the nature of the work done by him throughout the term. There is therefore every inducement to him to attend regularly to his practical and lecture work. Physiology includes histology, often combined with embryology, physiological chemistry, and physiology proper. Dr. Gaskell refers to the method of teaching mentioned by Professor Rose Bradford but adds another—namely, "seminars." These, we gather, are something like a "recitation" but the classes are very small and may, perhaps, be compared with the work done amongst us by students reading with a coach. Another method which obtains specially at *Harvard*, and *which Dr. Gaskell* considers of great value, is the system whereby a student is allotted a subject upon which he has to write a thesis which has to be read and discussed by the students, fellows, and teachers and defended by himself. He is expected to show a knowledge of the contemporary and other literature dealing with the subject of the thesis. The anatomical and physiological laboratories are far ahead, in Dr. Gaskell's opinion, of most of our own and the system of laboratory units as existing at Toronto and Johns Hopkins University impressed him very much. By this system only some 25 be utilised for most of the school year to maintain a comparatively pure air, but even these methods would fail when most wanted, as in summer. For large schools direct mechanical movement of the air was best by large fans running at low speeds. In order to avoid "short-circuiting" by opening of doors all ducts should be as large as could be afforded and the outlets of low resistance; inlets to rooms should be high on the walls, outlets low; 2000 cubic feet per head per hour should be supplied. Accessory heating preferably by low pressure steam or water was advisable. The air should be well moistened. Cloakrooms and stairways must also be ventilated. At present the chief objection to the mechanical ventilation was the sense of loss of tone from want of sufficient skin stimulation by the smoothly flowing warmed air. Probably the system of the future would be one of large supplies of very moderately heated air moved by combined propulsion and extraction by fans, with accessory heating of rooms and free permission to open doors and windows.

The Exhibition.

The exhibition was conveniently held in the same building in which the sectional meetings of the Congress were held, the upper and lower floors being devoted to this purpose. A considerable portion of the exhibition was devoted to the architectural drawing of schools. Most of the plans show an elevation of three floors; on the one side there is a corridor, out of which the various class rooms open, and the same arrangement is repeated on each floor. In the basement provision is made for a bath which may be a swimming bath or more usually a shower bath. A gymnasium is always provided and is in most plans arranged as a building separate from the main block. The variety in the arrangements of the buildings is considerable but all plans provide for the gymnasium and for a bath in some form. A large portion of the exhibition was occupied by school desks in various forms; the general arrangements seemed to be to make the desk and seat to accommodate two children and various devices had been adopted to allow the children to stand up in their places and yet to bring the desk sufficiently near them to prevent them stooping over their work. This arrangement differs from that adopted in the English schools in that the desk is made continuous while the seats are separated for each child. Such an arrangement allows the teacher to pass behind the children and to give to each child room to stand up at the side of his place, whereas in the arrangement shown in the exhibition the teacher is at the side of the scholar and cannot pass behind him. Various mechanical arrangements were shown for adjusting the desk and seats to the varying size of the children, but of these, all more or less complicated, no mention need be made. Generally speaking, it may be said that the desks appear heavy and in most instances to have an excess of ledges for the accumulation of dust. One form of drawing stool may be especially mentioned as it is both ingenious in design and most comfortable to work at. It is shaped as a somewhat flattened horseshoe on four legs. At one end a pillar is fixed which carries a drawing board which can be adjusted at any angle and at any height. From the same pillar an arm projects which carries a stand on which the object to be drawn is placed. The student, male or female, sits on the other end of the horseshoe with the legs in the concavity, or if the student be a male he can sit on the stool in a straddle manner. The only objection that can be raised to such a stool is the fact that it occupies a considerable amount of floor space as compared with a chair, but in comparison to an easel it occupies but a small space.

The above may be said to be the main features of the exhibition. Mention, however, may be made of a simple form of hygrometer for school use. The advantage of knowing the amount of moisture in the atmosphere of the schoolroom is obvious and means can be taken to correct the defect. Some of the diagrams for instruction appear to be worthy of note and one showing the joints cut from a bullock would seem to be of considerable use in the education of girls in housekeeping. Some of the models illustrating the anatomy of the human frame would appear unnecessarily complicated for such simple facts as are required in the education of children. The typewriting machine as used by the blind is of interest. It in some way resembles the Brail system, but by the various combinations of six keys any letter can be made and the word is stamped out and can be read either by the blind person or by sight. The disadvantage of the process is its extreme slowness, for the formation of nearly every letter requires the keys to be depressed three times. Various models for the artificial lighting of rooms were shown. Although the structure and arrangements of the building differed from those commonly seen in English schools yet the arrangements had much to be commended. A school differing somewhat in detail but similar in the main was also seen. This school had, however, four floors and the large hall was situated over the gymnasium, at the corner of the square, of which the school formed two sides.

THE MOSELY COMMISSION.

THE reports of the various members comprising the Mosely Educational Commission to the United States of America have just been issued and form a volume which will, we think, prove of great value to those interested in education. The book, however, demands close study and the contents are not arranged in the most convenient manner for reference. Thus there is no index and the joint report which apparently summarises the conclusions of the Commissioners is barely one and a half pages in length. There is, in addition, a series of summaries of each report but if the reader wishes to find the opinions of the Commissioners upon any single point his search is by no means made easy. These omissions will, however, we have no doubt be rectified in a future edition when we hope to see a really good subject index added. The idea of the Commission was started in Mr. Mosely's mind by the excellent work which he noticed to be done by American employed on patrol duty immediately outside the buildings. Fire drills for members of the staff take place daily in the wards, every nurse being drilled in the practical use of the outside and inside hydrants. The Commissioners in Lunacy state in their report that the day rooms and dormitories were in good condition, that the beds and bedding were very clean, that the patients were in a satisfactory condition of dress and personal neatness, and that the medical records and case books were well kept and illustrated by excellent photographs. The committee of management states in its report that additions to the building to accommodate 60 male patients are being made at an estimated cost of £10,500. The amount expended on repairs, additions, alterations, and improvements amounted to £5265 during the year.

City of London Asylum, Dartford (Annual Report for 1903).—The average number of patients resident during the year was 561, comprising 254 males and 307 females. The admissions during the year amounted to 193—viz., 107 males and 86 females. Of these 184 were first admissions. Dr. Ernest W. White, the medical superintendent, states in his report that regarding the mental condition of the patients admitted 13 were suffering from general paralysis and 45 from acute and subacute melancholia. "We are still receiving many chronic patients who have been treated previously in other asylums or in single care and who come to us as fresh cases...... As vacancies occur they are filled; we do not confine ourselves to cases of recent origin or to those in which the prospect of recovery is good." The causation of insanity in the admissions included hereditary predisposition, alcoholic intemperance, mental anxiety and worry, old age, and bodily diseases. The number of cases discharged as recovered during the year amounted to 59—viz., 31 males and 28 females, or 10·5 per cent. of the average number resident. The deaths during the year amounted to 48, or 8·5 per cent. as calculated on the same basis. Of the deaths two were due to epilepsy, three to renal disease, four to senile decay, five each to colitis and cardiac disease, six to pulmonary and other forms of tuberculosis, 11 to general paralysis of the insane, and the rest to other causes. The sewage system of the asylum has been thoroughly tested and defects have been remedied, iron pipes being substituted for earthenware in the vicinity of the well. "I may add," says Dr. White, "we have been almost free from dysentery since the change of water-supply." Apart from the occurrence of a few cases of dysentery [illegible]
good during the year. [illegible]
year's working of £1 [illegible]
state in their report th [illegible]
in their behaviour, that their dress and personal tidiness were satisfactory, that the condition of the wards, dormitories, and asylum generally was very favourable, and that the medical case-books were well kept. "As respects means of escape in case of fire we think there should be an additional exit from the single room end of F 4 ward and from both hospital dormitories, and we are glad to learn that the matter has already received the attention of the committee." The committee of management states in its report that a sanitary annexe has been added to the workshop block, that a greenhouse has been erected for plants required for the wards and gardens, that minor alterations have been made in the laundry dayroom, and that the fire extinction appliances throughout the asylum have been thoroughly overhauled.

SEWERAGE OF AXMINSTER.—The Local Government Board is urging the Axminster (Devon) rural district council to carry out the work of the sewering of the town at an early date. The district council, however, is taking no steps in the matter and the chairman at a recent meeting stated that the question had been under discussion for the past 30 years. At the present time open sewers in some cases run close to houses and public highways.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Dr. J. F. J. Sykes, medical officer of health of the metropolitan borough of St. Pancras, has been elected president of the Incorporated Society of Medical Officers of Health and will come into office on Oct. 1st. The society has *decided to make an investigation into the incidence and* causation of "return" cases of scarlet fever and diphtheria and as a first step a committee has been appointed to draw up a schedule of inquiries which medical officers of health and superintendents of isolation hospitals will be requested to adopt.

THE METROPOLITAN ASYLUMS BOARD AND ITS MEDICAL STAFF.

AGAIN we have to comment unfavourably upon the attitude adopted by the Metropolitan Asylums Board towards its medical staff, and in view of the several occasions on which we have considered it our duty to deal with this subject we think it as well at once to disclaim any personal animus in the matter. We know that for our medical readers such a disclaimer is unnecessary but the policy upon which we have commented has not been initiated by medical men, while the situation that has been created is one in which the public is deeply interested. The public duties of the Metropolitan Asylums Board are far-reaching, onerous, and delicate and if that Board, by the tacit sanction of the Local Government Board, succeeds in alienating medical sympathy the sufferers will be the people of London and not the medical profession. The recent arbitrary dismissal of certain of the assistant medical officers of the Metropolitan Asylums Board has, as our readers know, led to the conviction of the Board as an unjust master. The Board has paid compensation to the medical men who were treated in a manner the legality of which the Board shrank from attempting to defend. It is presumably with the view of being able to continue oppressive tactics, but without risk of legal reprisal, that the form which we print below has been prepared for the signature of assistant medical officers accepting service under the Board. The form, we understand, is already in force although it is unlikely that as yet any, or at all events many, medical men have signed it.

METROPOLITAN ASYLUMS BOARD.

CONTRACT OF SERVICE.

Name ... ...
Appointment ... ...
... ... 1904.

I hereby acknowledge and agree —

1. That the salary agreed to be paid to me is £ : : per annum.
[illegible] order, £ : .
[illegible] mum].
2 [illegible]
3. [illegible]
4. [illegible] duty,
[illegible] hall be
[illegible] nd to
[illegible] liable
[illegible] ithout
previous suspension; and that in the event of such dismissal or suspension followed by dismissal I shall receive my salary up to the day on which I may be so dismissed or suspended
5. [illegible]
6. [illegible]
situation I will give one * [illegible]
to the steward the amount of one * 's wages.
7. That my attention has been called to the Poor-Law Officers' Superannuation Acts, 1896-97 and the provisions thereof explained to me
8. That I am liable at any time to be transferred to any other institution of the Board to serve in a similar capacity to that for which I am now appointed.

Signed ... ...
Date ... ...

Witness ... .
Occupation ... .

* Week or month.

The document is a perfectly clear one, needing but little explanation though calling loudly for comment. It has to be signed in the presence of the steward, which seems an odd arrangement, tending to make it appear that an assistant medical officer is particularly in a subordinate position to the steward, while the third clause of the contract places him under the jurisdiction of "superior officers," these being, we suppose, the four principal officers of the Board—viz., the medical superintendent, the chaplain, the matron, and the steward. The fourth clause provides for the legal dismissal of assistant medical officers in the summary manner which has already cost the Board loss of prestige and loss of money. The position of the Board is secured by the fifth clause, which makes it clear that no assistant medical officer is intended to obtain a longer tenure of his office than one month. We invite medical men who think of taking service under the Metropolitan Asylums Board to consider the situation, and we suggest that no one should sign such a document. It is not in the nature of things to be expected that all the assistant medical officers of the Metropolitan Asylums Board are likely to remain, or are likely to desire to remain, for any long period the servants of the Board. The position of assistant medical officer to the Metropolitan Asylums Board is not one that a medical man would consider as a career, while we are perfectly aware that inconveniences arise from giving lengthy tenure to subordinate appointments. But there is a difference between appointing a medical man to a post for such a long time that it becomes unfair to ask for his resignation, and hiring him in the way that the charwoman or the cook is hired, with freedom to get rid of him at a week's or a month's notice. We do not believe that the Metropolitan Asylums Board, under such a contract, will obtain the services of young medical men anxious to learn and to carry out the various duties appertaining to the administration of a hospital for infectious disease. The assistant medical officer, who has to be obtained in a hurry and has to do his work while a panic is on, knowing that however well he does it he will be dismissed summarily, has no proper opportunity either of learning the scientific treatment of disease or of discharging his functions towards the public. He will not be an efficient officer, and he will not have a fair opportunity of becoming one. There is, so far as we can see, no inducement for seeking the posts in the conditions now imposed.

The object of obtaining the signatures of the assistant medical staff of the Board to the obnoxious contract published above is very clear. The Board desires to get rid of medical men in slack times, the justification of the measure being, of course, economy. No economy will result and it is no use for imitation reformers to shout loudly to the contrary. If we mistake not, on the same plea of economy reductions have been made in the nursing staff of the Board, whereby the position has been brought about that within two or three months of dismissing nurses the Board is advertising for new nurses. Supposing that these vacancies have to be filled temporarily by institutional nurses at wages higher than those given by the Board to its regular staff, where will be the economy? At the present time we believe there may be no particular pressure on the accommodation of the fever hospitals of the Metropolitan Asylums Board, but do the managers of the Board believe that the laws of periodicity are going to be set aside to oblige their spendthrift attempts towards reform? What will happen if the Board finds itself short of medical men and short of nurses with anything in the nature of an epidemic to combat? It will be unable to obtain efficient assistance save by high payment. This situation was met in past days by the maintenance of a staff adequate for keeping open all the permanent wards. That arrangement is now obsolete, while the cutting down of *personnel* is continued with greater rigour. To bring the hospitals into a plight in which they cannot cope with an outbreak of disease is not economy. It is no more economy than it is to omit to take out an insurance policy against fire or death A ruinous risk is incurred for the sake of saving a premium.

The whole position is a very serious one and demands the attention of the public whose safety depends upon the proper administration and maintenance of the hospitals of the Board. And what we would urge upon the public is that they must not be deceived by any statements that the innovations upon which it has been our duty recently to reflect constitute economy. We do not say this because the so-called economical changes are being made at the expense of the medical profession but because they are being made against public policy. The superintendents are to be put upon fixed and inadequate allowances of coals and lighting. What is saved to the public purse when the expenses of the various meters and their annual repairs are considered? Vicarious dispensing is to be done by the assistant medical officers and the medical employés of the Board are to be liable to immediate dismissal and so on, but the net result will not be economy. The medical profession at first will feel irritated and then will resolve not to place themselves at the disposal of the Board. The Board will have to raise its pecuniary terms and will spend considerably more pounds in so doing than it has saved shillings by ill-judged methods. It is to be hoped that the Local Government Board will take an early opportunity of investigating the whole matter.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Woking Urban District.—Dr. R. W. C. Pierce embodies in his current annual report an interesting account of an outbreak of septic sore-throat which occurred in this district in October and November of 1903 and which was attributed to the consumption of milk derived from a certain farm. There were in all 98 houses invaded by cases of this septic sore-throat and of this total no less than 76 obtained their milk from one or other of two milk dealers who, in turn, derived their supply from a common, and the suspected, source. The remaining 22 houses took their milk from nine other different dealers and Dr. Pierce apparently thinks that the illness in these 22 houses may be explained by the following facts: (*a*) milkmen borrow milk from one another on their rounds; (*b*) householders occasionally buy extra milk from passers-by; (*c*) the conveyance of infection from one house to another; (*d*) the possibility of other milk from a different source being similarly impure; and (*e*) the general prevalence of sore-throat in the autumn. Possibly this endeavour to explain the origin of these outstanding 22 cases is the weakest part of an otherwise strong chain of evidence. On inspecting the cows at the suspected farm the course taken was to examine the milk yielded by each quarter of the udders of the 20 cows and the results are certainly instructive. From one cow dirty pinkish milk was drawn from one teat and normal milk from the other three teats; from another what appears to have been pus was drawn from two teats, while the third cow yielded somewhat similar results. In the case of the fourth cow three teats yielded this pus-like material and the remaining teat coagulated milk. Bacteriologically the milk yielded streptococci and staphylococci "similar, if not identical with those which had been found in swabs from the throats of persons affected." An interesting fact brought out by the investigation was that the external examination of the udders afforded no indication of the conditions which must obviously have been present in the interior. This outbreak led to an examination of all the milk-supplies in the district and the result, as was to be expected by anyone conversant with the filthy conditions obtaining in the cowsheds of England, was to show an excessive amount of dirt "indicating a great want of cleanliness in the production or handling of milk," a fact which is equally demonstrable by an examination of the sediment to be found in the milk jugs of our breakfast tables. The veterinary surgeon who subsequently examined the cows which yielded the pus came to the conclusion that the condition of the udders was due to the fact that the cows had not been "properly stripped and that organisms gained entrance from outside through the milk ducts in the process of milking."

Cardiff Port Sanitary District.—Dr. Edward Walford's report for the last quarter of 1903 contains a record of the bacteriological examination of the water-supply of certain vessels arriving in the port of Cardiff and the results are somewhat instructive. In each case the source of the water is recorded and the results of the bacteriological examinations which were made by Dr. H. A. Schölberg are stated as number of organisms per cubic centimetre both at 37° and 20° C. The variations in the numbers are remarkable. For instance, the water of a steamer which arrived at Cardiff on Nov. 28th and which took in water at Karachi, Suez, and Algiers contained ten organisms per cubic centimetre at 37° C. and 950 at 20° C. This water is classed as "good." At the opposite extreme we have the water of a steamer which arrived on Oct. 23rd and which had watered at Karachi and Algiers, but which contained no less than 12,800 organisms per cubic centimetre at 37° C. and 4160 at 20° C. This water is regarded as "impure." Of course there are many additional facts which it would be instructive to know—i.e., the precise method of storage in each case, the position of the tanks as regards exposure to heat or dust, and the dates at which they were last cleaned out. But these points notwithstanding, the figures are interesting. The manner in which we in England are dependent upon the foreigner not only for meat but also as regards the quality of such meat is illustrated by the Cardiff figures contained in the report under review. During the quarter ended Dec. 31st of last year there arrived at that port 3450 forequarters and 3450 hindquarters of beef and 30,544 carcasses of mutton. For the wholesomeness of all this food we are largely dependent upon the foreigner, for it can hardly be contended that the examination of the frozen carcass is nearly so satisfactory as the examination of the animal before and after death when all the viscera are available Against this large arrival of dead meat 411 live cattle and 294 live sheep were received.

Plympton St. Mary Rural District.—Mr. S. Noy Scott is not an enthusiast in the matter of sanatoriums for consumption and he thinks that a given sum of money invested in erecting well-built and properly situated houses would do more towards the permanent reduction of the death-rate from pulmonary tuberculosis than many times the same sum expended on the building and support of sanatoriums. Inasmuch as it is not possible to isolate even a small proportion of the total number of cases it is useless to attempt by sanatoriums alone to produce any marked effect upon the general prevalence of the disease. Mr. Scott is, however, well pleased with the work done by the Didworthy Sanatorium, as although all the patients do not recover most of them receive distinct benefit and are able to return to work.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8553 births and 5379 deaths were registered during the week ending April 9th. The annual rate of mortality in these towns, which had been 19·7, 18·7, and 18 7 per 1000 in the three preceding weeks, declined last week to 18·4 per 1000. In London the death-rate was 18·6 per 1000, while it averaged 18·3 per 1000 in the 75 large provincial towns. The lowest death-rates in these towns were 7·0 in Walthamstow, 7·1 in Hornsey, 7·5 in Willesden, 7·6 in East Ham, 10·3 in Leyton and in Northampton, and 11·2 in Smethwick; while the highest rates were 21·4 in Bolton, 21·5 in Manchester, 21·7 in Swansea, 22 8 in Leeds, 23·4 Wolverhampton, 24·8 in Birmingham, 26·2 in Bootle, 27·7 in Hanley, and 29·3 in Norwich. The 5379 deaths in these towns last week included 583 which were referred to the principal infectious diseases, against 540, 532, and 640 in the three preceding weeks; of these 583 deaths 222 resulted from whooping-cough, 183 from measles, 57 from diphtheria, 52 from diarrhœa, 35 from scarlet fever, 25 from "fever" (principally enteric), and nine from small-pox. No deaths from any of these diseases were registered last week in Hastings, Southampton, Reading, Northampton, Burton-on-Trent, Coventry, or Tynemouth; among the other towns the highest death-rates from the principal infectious diseases were recorded in Brighton, Norwich, Hanley, Wolverhampton, Birmingham, St. Helens, Warrington, Bolton, and Rotherham. The greatest proportional mortality from measles occurred in Brighton, Norwich, Hanley, Stockport, St. Helens, Salford, Rochdale, Burnley, and Rotherham; from scarlet fever in Warrington and Newport (Mon.); from diphtheria in Bradford and West Hartlepool; and from whooping-cough in Wolverhampton, Walsall, Birmingham, Aston Manor, Wallasey, Warrington, Bolton, Bury, Salford, and Swansea. The mortality from "fever" and from diarrhœa showed no marked excess in any of the large towns. Of the nine fatal cases of small-pox registered in these towns last week three belonged to London, two to Hull, and one each to Stockport, South Shields, Gateshead, and Newcastle-on-Tyne. The number of small-pox cases remaining under treatment in the Metropolitan Asylums hospitals, which had been 74, 110, and 126 on the three preceding Saturdays, had further risen to 134 on Saturday, April 9th; 25 new cases were admitted during the week, against 26, 54, and 42 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 1505, against 1634, 1585, and 1570 at the end of the three preceding weeks; 141 new cases were admitted during the week, against 176, 145, and 153 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 375, 383, and 370 in the three preceding weeks, further declined to 333 last week, but were 96 in excess of the number in the corresponding period of last year. The causes of 68, or 1·3 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Newcastle-on-Tyne, and in 34 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Burnley, Halifax, Rotherham, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 23·0, 22·3, and 20·6 per 1000 in the three preceding weeks, further declined to 20·3 per 1000 during the week ending April 9th, but was 1·9 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 16·1 in Paisley and 17·9 in Edinburgh to 23 9 in Dundee and 24·6 in Perth. The 671 deaths in these towns included 19 which were referred to whooping-cough, 14 to measles, seven to small-pox, seven to diarrhœa, five to diphtheria, three to "fever," and two to scarlet fever. In all, 57 deaths resulted from these principal infectious diseases last week, against 85, 86, and 72 in the three preceding weeks. These 57 deaths were equal to an annual rate of 1·7 per 1000, which was 0·3 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 24, 29, and 23 in the three preceding weeks, further declined last week to 19, of which seven were registered in Aberdeen, six in Glasgow, three in Dundee, and two in Edinburgh. The deaths from measles, which had been 22, and 23 in the two preceding weeks, declined again to 14 last week and included eight in Glasgow, two in Dundee, and two in Paisley. The fatal cases of small-pox, which had been seven, seven, and five in the three preceding weeks, rose again last week to seven, of which four occurred in Greenock and three in Glasgow. The deaths from diarrhœa, which had been 18, 15, and nine in the three preceding weeks, further declined to seven last week and included three in Glasgow and two in Aberdeen. The fatal cases of diphtheria, which had been three, seven, and three in the three preceding weeks, rose again last week to five, of which three were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 185, 165, and 157 in the three preceding weeks, further declined last week to 138, but were 40 in excess of the number in the corresponding period of last year. The causes of 23, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·7, 30·4, and 28·5 per 1000 in the three preceding weeks, rose again to 29·7 per 1000 during the week ending April 9th. During the past four weeks the death-rate has averaged 29·1 per 1000, the rate during the same period being 18·7 in London and 19 5 in Edinburgh. The 216 deaths of persons belonging to Dublin registered during the week under notice showed an excess of nine over the number in the preceding week and included 19 which were referred to the principal infectious diseases, against 20, 14, and 20 in the three preceding weeks; of these, eight resulted from whooping-cough, four from measles, three from "fever," two from diphtheria, and two from diarrhœa, but not any from small-pox or from scarlet fever. These 19 deaths were equal to an annual rate of 2·6 per 1000, the death-rates last week from the principal infectious diseases being 2·3 in London and 0·8 in Edinburgh. The fatal cases of whooping-cough, which had been 13, five, and 11 in the three preceding weeks, declined again last week to 8. The deaths from measles, which had been four, five, and four in the three preceding weeks, were again four last week. The fatal cases of "fever," which had been one and two in the two preceding weeks, further rose last week to three. The two deaths from diarrhœa corresponded with the number in the preceding week. The 216 deaths in Dublin last week included 41 of children under one year of age and 48 of persons aged 60 years and upwards; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a decline. One inquest case and two deaths from violence were registered, and 91, or more than 42 per cent., of the deaths occurred in public institutions. The causes of nine, or over 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

The following appointments are notified:—Deputy Inspectors-General: T. D. Gimlette to Hong-Kong Hospital and L. H. Kellett to Plymouth Hospital. Fleet Surgeons: J. L Barrington to Haulbowline Hospital H. R. Osborne to the *Good Hope*; W. Bett to the *Russell*; E. B. Townsend to the *Britannia*, for Dartmouth sick quarters; and J. H. Stenhouse to the *Spartan*. Staff Surgeon W. H. S. Stalkartt to the *Monmouth*. Surgeon J. Fullarton to the *Cadmus*.

Royal Army Medical Corps.

Lieutenant J. Waddell is placed on temporary half-pay on account of ill-health (dated March 11th, 1904).

Army Medical Reserve of Officers.

Surgeon-Captain G. A. Lang, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers.

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 7th Lancashire: The appointment of Joseph Grant-Johnston to a Surgeon-Lieutenancy is cancelled.

Rifle: 2nd Volunteer Battalion the King's (Liverpool Regiment): Captain D. Smart, from the Liverpool Volunteer Infantry Brigade Bearer Company, to be Surgeon-Captain and to be borne as Supernumerary whilst doing duty with the above Bearer Company (dated April 2nd, 1904); Lieutenant J. G. Martin, from the Liverpool Volunteer Infantry Brigade Bearer Company, to be Surgeon-Lieutenant and to be borne as Supernumerary whilst doing duty with the above Bearer Company (dated April 2nd, 1904). 2nd Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant T. H. Livingstone resigns his commission (dated April 2nd, 1904). 9th Lanarkshire: Surgeon-Lieutenant W. J. Mackinnon to be Surgeon-Captain (dated April 2nd, 1904).

Deaths in the Services.

Inspector-General Timotheus J. Haran, R N. (retired), at his residence in London, in his seventy-fifth year. He entered the Royal Navy as assistant surgeon in 1850, became staff surgeon in 1858, fleet surgeon in 1871, and reached the rank of inspector-general in 1886. He retired two years later. In 1851 he was assistant surgeon of and employed in charge of the *Harlequin's* boats in the attack on Lagos (mentioned in despatches), and he was also present in several subsequent expeditions to the rivers and lagoons adjoining against the expelled chief Kosoko. He was also employed repeatedly in boat cruising in the *Harlequin's* boats for the purpose of suppressing the slave trade on the West Coast of Africa. During the Crimean war he was assistant surgeon of the *Viper* in the Black Sea and was repeatedly in action. He took part in the battle of Eupatoria, the operations on the coast of Circassia, including the capture of Kertch, and the expedition in the Sea of Azov, the night attacks on the sea defences of Sevastopol, the capture of Kinburn, and the subsequent operations in the Gulf of Dneiper (Crimean and Turkish medals, the Azoff and Sevastopol clasp). He was assistant and additional surgeon of the *Boscawen*, flagship of the Hon. Sir F. W. Grey on the Cape of Good Hope and West Coast of Africa station, between 1857 and 1860 and landed at Ascension to attend yellow fever cases of the *Trident* in 1859. He was surgeon of the *Brisk* from 1860 to 1863, being employed at the Cape of Good Hope and East and West Coasts of Africa, and accompanying Commodore Wilmot in December, 1862, on a mission to the King of Dahomey—an enterprise then considered perilous and which entailed an absence from ship of six weeks. He was selected for service with the Royal Marine battalion which proceeded to South Africa in 1879. In 1881 he was employed at Haslar and was afterwards in charge of the Malta hospitals up to the year 1886, when he was promoted to inspector-general and appointed to Plymouth Hospital. Inspector-General Haran was a justice of the peace of Queensland and was honorary surgeon to the King.

Staff Surgeon William Rogers, R.N. (retired), on April 7th, at his residence at Saltash, Cornwall. The deceased entered the Royal Navy as surgeon in 1839 and was promoted to staff surgeon on Oct. 20th, 1845. He had seen no war service. Since his retirement he had lived at Saltash where he was much respected.

Colonel Robert de la Cour Corbett, D.S.O., R.A.M.C., principal medical officer of the Oudh and Rohilkhund districts, at Lucknow, on March 24th, aged 59 years. He entered the service in 1867 as assistant surgeon, became surgeon in 1873, surgeon-major in 1879, brigade-surgeon in 1893, and surgeon-colonel in 1898. He served with the Burmese expedition in 1886–87, during the later part of the campaign acting as principal medical officer of the Upper Burmah Field Force (mentioned in despatches, D.S.O., medal and clasp).

Lieutenant Colonel Nathaniel Alcock, A.M.S. (retired), at Bellevue, Ballybrack, co. Dublin recently. He joined the army in 1860, became surgeon in 1873, surgeon-major in 1875, and retired in 1889. He served in the Kaffir war of 1878 (medal). He had been employed for some time as medical officer in charge of the military prison, Dublin. The deceased was a much esteemed and deservedly popular medical officer who possessed considerable literary and scientific attainments. The loss of health mainly brought about by field service and exposure in the Kaffir war, unfortunately led to his comparatively early retirement, by which the Army Medical Service lost an able and promising member.

Dentistry in the Army.

It is only of late years that the importance of dentistry has been recognised by military authorities. A soldier to go through an arduous campaign with efficiency must keep in good health, but unless his teeth are in good order he cannot masticate his food properly and his digestion will therefore be defective. Military rations in the field are not always readily assimilable; on the contrary, they are often supplied in a highly indigestible form, so the soldier more than the civilian should have every part of his assimilating apparatus in good working order. In the *Deutsche Militärarztliche Zeitschrift* for January Dr. Richter discusses the subject of military dentistry at considerable length. It was in Saxony that steps first were taken to instruct soldiers how to take care of their teeth. On April 3rd, 1902, a Ministerial circular containing instructions regarding the hygiene of the mouth was issued and in the following March a similar procedure was generalised for the whole of the German army. Lectures on the subject by qualified medical officers have also been instituted and non-commissioned officers are required to see that the inculcated theories are carried out. A few dental dispensaries are now in operation in some of the chief garrisons of Saxony and Bavaria, including Dresden and Leipsic, the charges being extremely moderate. Tooth-stopping, for example, costs 6*d.* only and a denture of eight teeth can be fitted for 7*s.* The *personnel* of these dispensaries is furnished by the dentists (qualified and probationary) who are fulfilling their term of compulsory military service. The reason that these establishments are as yet comparatively few in number is not due to budgetary restrictions, for the expenditure involved is trifling, but to the fact that dentists in Germany are extremely scarce. Whereas close on 30,000 medical men are engaged in the active exercise of their profession throughout the empire the total number of dental surgeons does not exceed 1800. And yet, according to Dr. Richter, the scope for skilled dentistry is considerable. Out of 1000 persons examined by him he found that on an average each individual had 5·9 teeth in his mouth that were more or less decayed. A perfectly sound set of teeth was extremely rare. In an infantry regiment there would be need, he says, of 2300 tooth extractions every year, 2100 teeth would require stopping, and 50 men would be candidates for dentures, partial or complete. Every recruit, continues Dr. Richter, should be taught that with care the usefulness of his teeth can be greatly increased and their duration prolonged. Caries in his opinion is not hereditary. Every night before going to bed the mouth should be thoroughly rinsed and the teeth well scrubbed with a wet brush. Unless this is done fermentation will take place, acids will be generated, and decay facilitated. During the daytime the mouth is seldom as quiescent as it is during sleep. Talking serves to keep the teeth clean and toothpicks after meals are very useful. Dentifrices and washes, in Dr.

Richter's opinion, are worse than useless. Nothing can be better than mechanical cleansing with a wet brush.

A BRITISH OFFICER'S REPORT ON THE FIGHT AT CHEMULPO.

A long extract from a letter by Captain Lewis Bayly of H.M.S. *Talbot*, dated Feb. 20th, has been published, from which we reproduce (from the *Standard* of April 12th) the following very interesting medical details connected with a naval engagement in modern war:—

wounded were out of this [illegible], which is [illegible] per cent. killed, [illegible] per cent. wounded. It must not be forgotten that having no gun shields her gun crews were practically unprotected and that shrapnel shell were largely used, to judge by the holes in the boats, funnels, &c. All was quiet in the engine room, as though they had been at target practice. In one stokehold (they have five with no fore and aft bulkhead) the water came up to the floor of the furnaces but did not get into the other stokeholds.

Further on and at the end of his communication Captain Bayly goes on to add that—

A very great deal of shrapnel must have been fired at the *Varyag*, judging by the round holes, and not much lyddite, for there seems to have been no inconvenience from poisonous gases. Much trouble has been caused to the wounded on account of the pieces of cloth that are constantly being extracted. Many men are wounded with punctures, holes about as large as the top of the little finger, and from a quarter of an inch to half an inch or one inch deep, but with no foreign substance such as iron, &c., being present in the wound, and no sign of scorching round the mouth of the wound.

THE WAR IN THE FAR EAST.

The Japanese Red Cross Society has a roll of between 800,000 and 900,000 members and its organisation leaves little if anything to be desired. Nearly 300 medical men are employed in its service and some 1600 qualified nurses are ready for immediate work in connexion with the war. The two permanent hospital ships of the society have accommodation for 400 patients.

The *Times* states that "200 Canadians who served in South Africa with medical and bearer corps have been engaged by the Japanese Government to serve in the present war in a similar capacity. The Japanese authorities have shown a complete knowledge of Canadian participation in the South African war in the selection they have made."

The executive committee of the Russian Red Cross Society, says the *Novosti*, has received advice from Athens that in the Russian Embassy there many Greek medical men have enrolled their names with the request that they may be sent to the theatre of war to serve in the hospitals.

THE LATE FREDERICK CHARLES STEARN, SURGEON, R.N.

The funeral of Surgeon F. C. Stearn, one of the medical officers of Portsmouth Dockyard, took place on April 6th with full naval honours. The service in the Dockyard church was held by the Rev. Dr. Shone and was attended by Rear-Admiral Henderson and all the Dockyard officers, Flag-Captain Sir R. K. Arbuthnot representing the Commander-in Chief. Afterwards a procession was formed, headed by a firing party. Then came the band of the Royal Naval Barracks, preceded by a field gun carriage on which was the coffin covered with a Union Jack and bearing the deceased officer's hat and sword. Six surgeons were pall bearers. Carriages with private mourners followed and after them walked a large number of naval and Dockyard officers. The interment was at the Highland-road Cemetery and at the close of the service the usual three volleys were fired over the grave.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on April 12th, Sir J. N. Dick, K.C.B., being in the chair, the sum of £50 was distributed among the several applicants.

The *Army and Navy Gazette* of April 9th states that Surgeon-General G. J. Evatt, C.B., retired list, A.M.S., has been invited to contest the Fareham Division of Hampshire at the general election in opposition to the sitting member, Mr. A. H. Lee, Civil Lord of the Admiralty.

"Audi alteram partem."

SYPHONAGE IN THE GREAT INTESTINE.

To the Editors of THE LANCET.

SIRS,—A reference to Dr. R. W. Leftwich's latest work on "Syphonage and Hydraulic Pressure in the Large Intestine" has served to confirm the opinion I formed from the evidence produced in his earlier papers—viz., that he is in error in supposing the great intestine to act as a syphon in man during life. The chief observations on which he bases his theory of syphonage are (putting them in brief) the following:—

1. That a piece of garden hose, bent so as to represent the various curves and segments of the colon, acts as a syphon with substances which are only partially fluid in nature, such as glycerine. The criticism I offer to this observation is that the normal contents of the great intestine are of such a consistency that they cannot be made to flow in a tube even with rigid walls, much less in one with flexible and unequal walls. Further, the curves given by Dr. Leftwich to his artificially constructed colon have no resemblance to the actual flexures of the colon as seen in the human body, either living or dead.

only full and
nd fixation of
Leftwich had
e arrangement
in animals allied to man or to consult the literature on this subject, otherwise he would have found that the disposition of the great intestine of man does not differ in principle from that found in other mammals, in which, he is careful to explain, there can be no colic syphonage. It is certainly true amongst genera of primates that the more they are habituated to the upright posture the more firmly is their great intestine fixed to the posterior abdominal wall, but this feature finds a full and satisfactory explanation in the alterations in the respiratory movements of the abdominal viscera and need for greater fixation of the abdominal contents, caused by the change of posture.

3. That the theory of syphonage explains the arrangement of the fibres of the muscular coats of the human colon. The muscular arrangement of the human colon is not peculiar, it is similar to that of all mammals which live on a mixed or vegetable diet and in which the contents of the
s of a solid consistency. The
muscular coat of the colon in
e production of the peculiar
peristaltic movements which help in the digestion, absorption, and propulsion of the semi solid contents of the colon.

4. That the tonicity or contraction of the tænia of the colon can render the walls of that viscus rigid and thus fit it to act as a syphon. No one, so far as I know, has ever denied tonicity to either the longitudinal or circular coat of the colon, but I am unable to conceive that the action of the longitudinal coat can have any effect on the bowel other than to shorten it. The only manner in which the walls of the bowel could be rendered rigid enough to serve as a syphon would be to suppose that the circular fibres of the colon, which alone can alter the lumen, possessed an active power of elongation. Dr. Leftwich, however, in harmony with modern physiological teaching, regards such an action as impossible, but, on the other hand, he refuses to accept physiological evidence of the importance of the peristaltic movements of the great intestine, yet the muscular coat of six inches of the human colon is nearly three times the weight of an equal segment from the small intestine.

The only manner in which the cæcal or colic wall could be rendered rigid enough to serve for syphonage would be to create a negative pressure within the cavity of the abdomen. This effect could be obtained by placing the patients, not in the upright posture, as Dr. Leftwich places them to obtain colic syphonage, but in a head down posture, for we know that in such a posture the negative pressure within the abdomen is sufficient to cause *ballooning of the bladder*, vagina, or rectum if the orifices of these viscera be opened. In the upright posture, on the other hand, the intestinal contents are subjected to a pressure of from 10 to 20 millimetres of mercury, the pressure rising three or five millimetres with each expiration, from 20 to 30 millimetres with persons aged 60 years and upwards; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a decline. One inquest case and two deaths from violence were registered, and 91, or more than 42 per cent, of the deaths occurred in public institutions. The causes of nine, or over 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Deputy Inspectors-General: T. D. Gimlette to Hong-Kong Hospital and L. H. Kellett to Plymouth Hospital. Fleet Surgeons: J. L Barrington to Haulbowline Hospital H. R. Osborne to the *Good Hope;* W. Bett to the *Russell;* E. B. Townsend to the *Britannia*, for Dartmouth sick quarters; and J. H. Stenhouse to the *Spartan*. Staff Surgeon W. H. S. Stalkartt to the *Monmouth*. Surgeon J. Fullarton to the *Cadmus*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant J. Waddell is placed on temporary half-pay on account of ill-health (dated March 11th, 1904).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain G. A. Lang, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 7th Lancashire: The appointment of Joseph Grant-Johnston to a Surgeon-Lieutenancy is cancelled.

Rifle: 2nd Volunteer Battalion the King's (Liverpool Regiment): Captain D. Smart, from the Liverpool Volunteer Infantry Brigade Bearer Company, to be Surgeon-Captain and to be borne as Supernumerary whilst doing duty with the above Bearer Company (dated April 2nd, 1904); Lieutenant J. G. Martin, from the Liverpool Volunteer Infantry Brigade Bearer Company, to be Surgeon-Lieutenant and to be borne as Supernumerary whilst doing duty with the above Bearer Company (dated April 2nd, 1904). 2nd Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant T. H. Livingstone resigns his commission (dated April 2nd, 1904). 9th Lanarkshire: Surgeon-Lieutenant W. J. Mackinnon to be Surgeon-Captain (dated April 2nd, 1904).

DEATHS IN THE SERVICES.

Inspector-General Timotheus J. Haran, R N. (retired), at his residence in London, in his seventy-fifth year. He entered the Royal Navy as assistant surgeon in 1850, became staff surgeon in 1858, fleet surgeon in 1871, and reached the rank of inspector-general in 1886. He retired two years later. In 1851 he was assistant surgeon of and employed in charge of the *Harlequin's* boats in the attack on Lagos (mentioned in despatches), and he was also present in several subsequent expeditions to the rivers and lagoons adjoining against the expelled chief Kosoko. He was also employed repeatedly in boat cruising in the *Harlequin's* boats for the purpose of suppressing the slave trade on the West Coast of Africa. During the Crimean war he was assistant surgeon of the *Viper* in the Black Sea and was repeatedly in action. He took part in the battle of Eupatoria, the operations on the coast of Circassia, including the capture of Kertch, and the expedition in the Sea of Azov, the night attacks on the sea defences of Sevastopol, the capture of Kinburn, and the subsequent operations in the Gulf of Dneiper (Crimean and Turkish medals, the Azoff and Sevastopol clasp). He was assistant and additional surgeon of the *Boscawen*, flagship of the Hon. Sir F. W. Grey on the Cape of Good Hope and West Coast of Africa station, between 1857 and 1860 and landed at Ascension to attend yellow fever cases of the *Trident* in 1859 He was surgeon of the *Brisk* from 1860 to 1863, being employed at the Cape of Good Hope and East and West Coasts of Africa, and accompanying Commodore Wilmot in December, 1862, on a mission to the King of Dahomey—an enterprise then considered perilous and which entailed an absence from ship of six weeks. He was selected for service with the Royal Marine battalion which proceeded to South Africa in 1879. In 1881 he was employed at Haslar and was afterwards in charge of the Malta hospitals up to the year 1886, when he was promoted to inspector-general and appointed to Plymouth Hospital. Inspector-General Haran was a justice of the peace of Queensland and was honorary surgeon to the King.

Staff Surgeon William Rogers, R.N. (retired), on April 7th, at his residence at Saltash, Cornwall. The deceased entered the Royal Navy as surgeon in 1839 and was promoted to staff surgeon on Oct. 20th, 1845. He had seen no war service. Since his retirement he had lived at Saltash where he was much respected.

Colonel Robert de la Cour Corbett, D.S.O., R.A.M.C., principal medical officer of the Oudh and Rohilkhund districts, at Lucknow, on March 24th, aged 59 years. He entered the service in 1867 as assistant surgeon, became surgeon in 1873, surgeon-major in 1879, brigade-surgeon in 1893, and surgeon-colonel in 1898. He served with the Burmese expedition in 1886–87, during the later part of the campaign acting as principal medical officer of the Upper Burmah Field Force (mentioned in despatches, D.S.O, medal and clasp).

Lieutenant Colonel Nathaniel Alcock, A.M.S. (retired), at Bellevue, Ballybrack, co. Dublin recently. He joined the army in 1860, became surgeon in 1873, surgeon-major in 1875, and retired in 1889. He served in the Kaffir war of 1878 (medal). He had been employed for some time as medical officer in charge of the military prison, Dublin. The deceased was a much esteemed and deservedly popular medical officer who possessed considerable literary and scientific attainments. The loss of health mainly brought about by field service and exposure in the Kaffir war, unfortunately led to his comparatively early retirement, by which the Army Medical Service lost an able and promising member.

DENTISTRY IN THE ARMY.

It is only of late years that the importance of dentistry has been recognised by military authorities. A soldier to go through an arduous campaign with efficiency must keep in good health, but unless his teeth are in good order he cannot masticate his food properly and his digestion will therefore be defective. Military rations in the field are not always readily assimilable; on the contrary, they are often supplied in a highly indigestible form, so the soldier more than the civilian should have every part of his assimilating apparatus in good working order. In the *Deutsche Militarärztliche Zeitschrift* for January Dr. Richter discusses the subject of military dentistry at considerable length. It was in Saxony that steps first were taken to instruct soldiers how to take care of their teeth. On April 3rd, 1902, a Ministerial circular containing instructions regarding the hygiene of the mouth was issued and in the following March a similar procedure was generalised for the whole of the German army. Lectures on the subject by qualified medical officers have also been instituted and non-commissioned officers are required to see that the inculcated theories are carried out. A few dental dispensaries are now in operation in some of the chief garrisons of Saxony and Bavaria, including Dresden and Leipsic, the charges being extremely moderate. Tooth-stopping, for example, costs 6*d.* only and a denture of eight teeth can be fitted for 7*s.* The *personnel* of these dispensaries is furnished by the dentists (qualified and probationary) who are fulfilling their term of compulsory military service. The reason that these establishments are as yet comparatively few in number is not due to budgetary restrictions, for the expenditure involved is trifling, but to the fact that dentists in Germany are extremely scarce. Whereas close on 30,000 medical men are engaged in the active exercise of their profession throughout the empire the total number of dental surgeons does not exceed 1800. And yet, according to Dr. Richter, the scope for skilled dentistry is considerable. Out of 1000 persons examined by him he found that on an average each individual had 5·9 teeth in his mouth that were more or less decayed. A perfectly sound set of teeth was extremely rare. In an infantry regiment there would be need, he says, of 2300 tooth extractions every year, 2100 teeth would require stopping, and 50 men would be candidates for dentures, partial or complete. Every recruit, continues Dr. Richter, should be taught that with care the usefulness of his teeth can be greatly increased and their duration prolonged. Caries in his opinion is not hereditary. Every night before going to bed the mouth should be thoroughly rinsed and the teeth well scrubbed with a wet brush. Unless this is done fermentation will take place, acids will be generated, and decay facilitated. During the daytime the mouth is seldom as quiescent as it is during sleep. Talking serves to keep the teeth clean and toothpicks after meals are very useful. Dentifrices and washes, in Dr.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Health of Convicts in the Andaman Islands.—The Increasing Plague Mortality.—Further Particulars of the Mulkowal Disaster.

THE annual report on the penal settlement of the Andaman Islands has recently been published. The islands are admittedly unhealthy and the chief diseases are malaria, dysentery, and phthisis. Phthisis is said to be encouraged by insufficient lateral sleeping-floor area in the convict barracks and by insufficient clothing, especially during the rains. Against malaria mosquito brigades have been started in every station and village in the settlement and the general administration of quinine is to be extended further. Some curious remarks are made in the report concerning the use of the mosquito net. It is considered impracticable because it interferes with the perflation of air. I quite agree that "to prevent the insidious infection of phthisis there must be the freest perflation of air possible in dwellings," but that this view "prohibits the mosquito net as a remedy for malaria in Port Blair Convict Barracks" is questionable. The report goes on to say that "as both phthisis and malaria are equally dangerous in the settlement a choice must be made between free perflation of air and the mosquito net, and since the mosquito brigade is a good remedy for malaria the mosquito net may be left out on consideration." Here we have the writing of a civilian and not that of the medical officer. The mosquito net does interfere somewhat with the currents of air but not sufficiently for it to be condemned on that account, and its manifest advantages in preventing a malarious patient being dangerous to others should have insured its use. The want of floor space—in other words overcrowding—would seem to be the chief evil.

The period of the annual plague maximum mortality throughout India is now approaching and the death-rate has been steadily rising. The total number of deaths from plague last week was 33,517, being nearly 5000 more than in the previous seven days. The principal increases are recorded in the United Provinces, the Punjab, the Bombay Presidency, and Bengal. The totals published are: Punjab, 6431 deaths; Bengal, 4386; Bombay Presidency, 7140; Bombay city, 925; Karachi, 145; Calcutta, 230; Madras Presidency, 625; Central Provinces, 2290; Mysore State, 383; Hyderabad State, 577; Central India, 955; Rajputana, 621; and Kashmir, 405. It is a curious circumstance that the outbreaks in Bombay city and in Calcutta are both behind their usual seasonal developments. The recrudescence in Karachi is very severe and Allahabad has also recently suffered tremendously.

The mystery of the Mulkowal disaster is gradually leaking out. It appears that the Plague Research Laboratory of Bombay notified the Punjab Government of its inability to supply the full quantity of the prophylactic and at the same time intimated that the fluid which would be sent would be prepared in a different way. It was soon noticed that a much larger proportion of the new fluid was unfit for use—in fact, I have it from one of the operators that the number of bottles he thought it advisable to discard was very considerable. It was reported that abscesses occurred more frequently with the new fluid which suggested that it contained impurities. Moreover, the reaction was feeble and the occurrence of a few deaths closely following inoculation threw further suspicion on the new fluid. While arrangements were being made to discontinue its use the deplorable calamity occurred. 19 persons were inoculated from one bottle and all of them contracted tetanus and died. No blame is attached to the inoculating officer. The circumstances point to the conclusion that the fluid had been contaminated before it reached the Punjab. How this particular bottle became poisoned still remains a mystery. The disaster has proved a death-blow to inoculation in India.

March 26th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Work of the Port Sanitary Authority during 1903; Liverpool and Sea-borne Infectious Disease.

IN an important seaport like Liverpool, which is open to ships carrying merchandise and passengers from all parts of the world, there is no small liability of infectious disease when it may happen to exist on incoming vessels being brought to the port. The port sanitary authority by careful watchfulness is guarding against the occurrence of such mischief, being aided in this effort by the Mersey Docks and Harbour Board. In the report of the port sanitary authority for 1903, recently issued, Dr. E. W. Hope deals with the manner in which disease is combated when a vessel on arrival in the Mersey is suspected of being infected with any infectious disease. She is at once boarded by the medical officer and is not permitted to dock until he has thoroughly examined her. If the vessel be found free from disease the captain receives a certificate to that effect and is then allowed to take his vessel to dock. The report states that there are statutory powers authorising the detention of vessels infected, or believed to be infected, with cholera, plague, and yellow fever, but there are no statutory powers to prevent other ships which may have small-pox, typhus fever, &c., on board from entering the docks. However, by an arrangement with the Mersey Docks and Harbour Board, any dangerously infected vessel may be prevented from entering the docks until dealt with by the medical officer. Thanks to this valuable provision the port of Liverpool is exceptionally well protected. With regard to the hospital accommodation it is mentioned that the original port hospital in the Sloyne has recently been added to and improvements have been made in bathing and lavatory accommodation. An additional pavilion and a separate home for the nurses, as also a laundry and a disinfecting apparatus, were erected in 1902. There is now accommodation for 50 patients. Patients suffering from infectious disease and requiring to be removed to the port hospital are conveyed by the port sanitary authority's tug or by the ship's boat to the hospital jetty and landed. The majority of patients, however, are removed to the city hospitals from the dock after the vessel has been berthed, this being a more convenient plan than sending all sea-borne cases to the port hospital. The number of ships from infected ports medically inspected during the year was 119 and vessels bound for Manchester (*viâ* Ship Canal) from infected ports are dealt with by the Liverpool port sanitary authority under an order of the Local Government Board. The Liverpool authority has also accepted responsibility for the accommodation in a Liverpool hospital of any case of small-pox which may be present on board a Manchester-bound vessel. This is a voluntary arrangement between the authorities of Liverpool and Manchester. There is an interesting paragraph in the report about rats as disseminators of plague. Many methods have been tried to catch these pests but trapping has yielded, so far, the best results. This can only be done properly by expert rat catchers. Rats when caught are sent to the corporation bacteriologist who reports on the presence of plague amongst them, or they are killed and the carcasses destroyed in the ship's furnaces. During last year 5083 rats were caught on board 98 ships, but none were found to be infected with plague. Several pages in the report are occupied by a codification of the modifications in quarantine measures and the additional regulations regarding rats which are the outcome of the International Sanitary Convention in Paris in October last. On the subject of yellow fever Dr. Hope points out that it is now concluded that this disease, like malaria, is transmitted by a species of mosquito found plentifully in the haunts of yellow fever. During the year 16 ships brought cases of small-pox, or suspected small-pox, to the port, notably from Bilbao, Barcelona, Constantinople, and Smyrna. 32 cases of enteric fever, six cases of scarlet fever, 12 cases of measles, one case of anthrax, 32 cases of phthisis, and 18 cases of beri-beri occurred in Liverpool-bound vessels and were reported to the authority. As to the emigrants, only 79 out of the large total of 265,918 were found to be suffering from infectious disease. These were children affected with small-pox, chicken-pox, measles, and scarlet fever. During the year the port has remained entirely free from those forms of sickness which tend to cause interference with commercial business by leading to quarantine in foreign ports.

Birkenhead Infectious Diseases Hospital.

The desirability of providing increased accommodation at the Birkenhead Infectious Diseases Hospital has become a matter of urgency and the matter has engaged the attention of the health committee of the Birkenhead town council for some time past. The committee adopted a motion, which will require ratification by the town council, to the effect that various alterations and additions should be made at an estimated cost of about £13,000. This estimated expenditure will comprise £4294 for alterations and additions to the administrative block; £4940 for the erection of two additional ward pavilions, each to contain 12 beds, with day-room attached; £858 for a lodge and discharging block, to be erected at the main entrance to the hospital; £736 for the construction of a laundry block; £1050 for the provision of machinery, with the addition of a reserve boiler; and general furnishing about £1000.

The Harveian Oration at the Royal College of Physicians of London.

Dr. Richard Caton, consulting physician to the Royal Infirmary and emeritus professor of physiology at the University of Liverpool, is announced to deliver the Harveian Oration at the Royal College of Physicians of London in June next.

Infirmary for Children.

The appeal made by the committee of the Liverpool Infirmary for Children on behalf of the rebuilding fund has resulted in the receipt of £39,269 up to March 28th. £25,000 are still required to make up the desired amount.

Sanitary Inspectors' Examination Board.

On April 5th the first of a five days' examination, under the Sanitary Inspectors' Examination Board, took place at the University of Liverpool. This is the first occasion upon which the examination has been held in the provinces. Dr. Hope, the medical officer of health of Liverpool, had arranged the preliminary details of the examination. There were only 14 candidates, including several who had been trained at the Liverpool School of Hygiene.

Anthrax in Cheshire.

The Board of Agriculture has issued an order with regard to the slaughter of animals in cases of anthrax to the effect that the council of the administrative county of Chester may, if it thinks fit, cause to be slaughtered any animal affected with anthrax or suspected of being so affected. The slaughter of animals shall be conducted in such a mode as will, as far as possible, prevent effusion of blood. Where the animal slaughtered was affected with anthrax the owner shall be compensated to the extent of one half the value of the animal immediately before it became so affected and in every other case the compensation shall be the value of the animal immediately before it was slaughtered. Provided that the owner of the animal gives notice in writing to the council or its inspector or other officer that he objects to the animal being slaughtered, it shall not be lawful for the council to cause that animal to be slaughtered except by the further special authority of the Board of Agriculture and Fisheries being first obtained. On each occasion of slaughter under this article the council shall send to the Board of Agriculture and Fisheries a report stating the number of animals slaughtered, the mode of slaughter and of disposal of the carcasses, and the compensation paid in respect of each animal.

April 12th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Bristol.

BRISTOL has been entirely free from small-pox since the end of September last but it is probable that there will now be some cases infected by a tramp who slept in a large common lodging-house in the city on March 29th and who was found on April 2nd in the Keynsham workhouse suffering from the disease. The man had left Newcastle on-Tyne on March 13th, tramping south through Worcester and Gloucester. It is nearly eight years since small-pox was spread in Bristol through the agency of a common lodging-house and on that occasion there were 20 cases.

Vagrancy in Gloucestershire and Somersetshire.

In 1882 a County Vagrancy Committee was formed in Gloucestershire, three members being appointed by the Court of Quarter Sessions and one by each of the boards of guardians in the county. The chairman of this committee presents to the county council a quarterly report of considerable value, setting out the number of tramps who have visited the various casual wards during a specified period. In the first quarter of the present year 17,873 tramps were admitted to the wards of the Gloucestershire workhouses, an increase over the corresponding period of last year of 4147. This increase is almost entirely confined to the Gloucester, Westbury, and Winchcombe unions. At the last meeting of the county council the chairman of this committee made the satisfactory statement that there was a distinct decrease in the number of children being dragged about the country by tramps. At the meeting of the Somerset county council, held on April 4th, a motion was adopted urging the Local Government Board to consider what measures could be adopted for the establishment of a more effective and uniform system of dealing with tramps throughout the country.

Penybont Health Report.

Mr. Wyndham Randall, the medical officer of health of the rural district of Penybont in Glamorganshire, has just issued his annual report from whi [illegible] an estimated population of 15,455 [illegible] 1903 was 33 3 per 1000, the death-rate from all causes 14·7 per 1000, and the infantile mortality-rate as low as 99 per 1000 births. The county asylum is situated in the Penybont district and Mr. Randall records for several diseases the death-rates in the asylum alone and in the rural district excluding the asylum. In the asylum the phthisis death-rate was 16·6 per 1000 and the cancer death-rate 3·7 per 1000, while in the rural district the death-rate from these two diseases was 1 per 1000 and 0·6 per 1000 respectively.

Cornwall County Nursing Association.

The annual meeting of the Cornwall County Nursing Association was held at Truro on April 8th. It was reported that during 1903 six new districts had been formed, making a total of 34 district associations affiliated to the society. 42 nurses had been trained since the commencement of the work, of whom 26 are still working for the association. The financial statement showed that the income amounted to £361 and the expenditure to £660, the deficiency having been met by taking about £200 from the capital.

April 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The late Sir Philip Crampton Smyly.

THE death of Sir Philip Crampton Smyly came as a surprise in the end, although he had for some time been a severe sufferer from gout. His scientific attainments, no less than his social connexions, made him one of the most prominent representatives of the medical profession in the country. He had been President of the Royal College of Surgeons in Ireland and representative of the College on the General Medical Council and honorary surgeon to the late Queen Victoria. At his death he was honorary surgeon to the King. By his marriage with a daughter of the third Lord Plunket, he was brother-in-law to the Archbishop of Dublin and Lord Rathmore. Sir Philip Smyly was only ill for a few hours.

Ballinasloe District Lunatic Asylum.

Much interest has been felt in the West of Ireland for months as to who would be the successor to the late Mr. R V. Fletcher as resident medical superintendent of the Ballinasloe District Lunatic Asylum. The election, which was in the hands of the joint committee nominated by the Galway and Roscommon county councils, took place on April 11th and resulted in the appointment of Dr. James St. Lawrence Kirwan, recently the junior medical assistant in the asylum. A letter was read from the Lunacy Department, stating that the Lord Lieutenant concurred in the resolution of the board fixing the salary of the resident medical superintendent at £500 per annum with £120 a year as allowances.

The Freedom of the City of Belfast for Mrs. Pirrie.

The corporation of the city of Belfast has unanimously decided to confer the freedom of the city on Mrs. Pirrie. The compliment is paid "in recognition of her signal services to the community in inaugurating and raising by her untiring zeal and personal influence a fund sufficient for the erection, equipment, and endowment of the Royal Victoria Hospital, which was instituted to commemorate the Diamond Jubilee of Her late Majesty Queen Victoria and to confer lasting benefits upon the citizens of the city of Belfast."

The Right Hon. W. J. Pirrie has already had this honour conferred upon him in recognition of his great services to Belfast during the period of his Lord Mayoralty. It is unique in the annals of municipal life for husband and wife to have such honours bestowed upon them.

Health of Belfast.

Since the commencement of the present epidemic of small-pox in Belfast, 46 cases had been admitted to the Purdysburn Hospital, 30 were discharged, two died, and there were 14 still remaining in hospital. There were 147 admissions to the intercepting hospital and 16 "contacts" remain at present. Between Feb. 21st and March 19th there were notified 38 cases of scarlet fever, 24 of erysipelas, 20 of typhoid fever, 18 of diphtheria, 5 each of simple continued fever and small-pox, 4 of puerperal fever, and 2 of croup. The deaths from zymotic diseases were 56 and those from phthisis and diseases of the respiratory organs were 96 and 213 respectively, making a total of 309 from the last two causes. Very few cases of typhoid fever have been notified during the month. The deaths from whooping-cough keep high and the mortality from respiratory diseases has been exceptionally high of late. The prevalence of small pox in Glasgow accounted for its being carried to Belfast. It was strongly urged at the meeting of the city corporation on April 5th that something should be done to deal with the tuberculosis problem (96 deaths from consumption occurred in the past month) and it came out in the discussion that plans are to be considered shortly for a building to accommodate 100 patients.

The Belfast Ophthalmic Institution.

At the annual meeting of the friends of this charity, held on April 7th, it was reported that there were 171 intern and 2184 extern patients during the past year. The year closed with a debt of £54 in addition to one of £100 to the "alteration and additional building account." The honorary secretary said that if the committee would collect £100 before the next annual meeting he would augment it by £50 A vote of thanks was passed to the medical staff of the hospital for their services.

Newry Guardians and the Medical Officers of the Newry Union.

At a meeting of the South Down branch of the Irish Medical Association held in Newry on April 7th it was decided that the medical officers of the Newry union should write to the Newry board of guardians for instructions how to act in cases of emergency, because, as matters stand at present, they are precluded from having consultations except in ordinary cases in the daytime. In the latter cases the existing fee allowed by the guardians corresponds with that which they are prepared to accept but in all other cases which are most likely to arise every medical man practising in the neighbourhood refuses to accept the fees at present offered, and they feel that they must in the interest of their patients be placed in a position to be able to obtain immediate assistance in case of necessity so as to relieve suffering or to save human lives.

April 13th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Chloroform and Oxygen Anæsthesia.

AT a meeting of the Academy of Medicine held on March 29th M. Kirmisson gave an account of his experience in the use of chloroform mixed with oxygen as an anæsthetic, being a revival of a method which had been formerly tried by Paul Bert upon some patients under the care of Péan. M. Kirmisson uses Rede's apparatus and gives a mixture of vaporised chloroform and oxygen in the proportion of from two to three grammes of the former with from three to four litres of the latter. M. Kirmisson's experience of the method comprises 229 cases of anæsthesia in children aged from six months to 15 years. No untoward effects were observed. The anæsthetic sleep is perhaps rather longer in coming on than with chloroform alone, but, on the other hand, the period of excitement is absent and vomiting is very rare. By this method M. Kirmisson has kept a patient anæsthetised during an operation lasting 52 minutes with only 16 grammes of chloroform. He considers that the method will find its principal application in abdominal surgery and in gynæcology where operations are likely to be prolonged. The use of oxygen causes a slight increase in the expense of administration compared with that of chloroform alone but this is compensated by the saving in the amount of chloroform used.

A New Local Anæsthetic.

At the same meeting of the Academy M. Forneau and M. Billon gave an account of a new local anæsthetic which has the same properties as cocaine but is only half as poisonous. Moreover, it has no vaso constrictor power which is one of the chief objections to cocaine. The body belongs to the group of amino alcohols and its name is hydrochlorate of A-dimethyl-amino-B-benzoyl-prophenol, or more simply amyleine. M. Reclus and M. Chaput have used it in general surgery, M. de Lapersonne in ophthalmology, and M. Sauvez in dentistry, all with success.

Treatment of Cancer of the Skin by the X Rays.

Still at the same meeting M. Leredde gave an account of the above treatment. The therapeutic use of the x rays after a period of somewhat risky groping in the dark could now be applied under definite regulations, at all events to the treatment of malignant affections of the skin, in which really remarkable effects had been obtained. The forms of disease to which this method is specially applicable are those called by M. Leredde "*épithéliomes adultes*"—that is to say, those in which the field of altered tissue is limited by a raised edge (*bourrelet*). Such cases of epithelioma are serious or at all events tend to become serious. Cure is brought about by liquefaction and disintegration of the malignant tissues which are completely destroyed, showing the selective action of the rays upon cancerous tissue. If pain is present it often disappears after the first sitting and the same is the case with any offensive smell. The æsthetic results are excellent and cure may be considered as absolute when the treatment is pushed far enough. Radiotherapy may be combined with other measures but at present it is the treatment of election for certain localised growths such as epithelioma of the eyelids, epithelioma of the nose, and in many cases where the patient refuses the use of the knife.

The Isolation of the Tuberculous at Paris.

The fifth committee of the Municipal Council of Paris has given up the idea of establishing an isolation hospital at Montmorency owing to the opposition of the inhabitants and is now casting its eyes upon the Chateau of Dugny close to Bourget (Seine). The building lies in a plain and its interior arrangements would lend themselves well to the required purposes. It stands in a park with an area of 125 hectares, partly wood and partly meadow land, which is traversed by a little stream, the Morée. The principal building has a frontage of not less than 70 metres and the interior is divided into 200 rooms. M. Mesureur, the director of the Assistance Publique, estimates that 1000 tuberculous patients could be isolated at Dugny. The committee has been over the chateau and in the absence of any opposition the Assistance Publique thinks that the building will be ready for reception of the patients before the end of the current year. Besides this M. Mesureur proposes to hand over for the treatment of tuberculosis the annexe of the Hôtel Dieu, the Laennec and Broussais Hospitals, and the 27th Bastion. These will provide a total of 1184 beds of which 167 will be reserved for surgical cases. Various wards will be also allotted for tuberculous patients at the Tenon, Boucicaut, Saint Antoine and Saint Louis Hospitals providing another 909 beds. Finally, two anti-tuberculous dispensaries will be established, the one at the Tenon Hospital and the other at the Laennec Hospital. The expenses, which are estimated at about 2,000,000 francs, will be met partly by loan and partly out of the funds of the *pari mutuel*.

The Chemical Constitution of Living Beings.

At a recent meeting of the Academy of Sciences M. Quinton laid before those present the results of a long and patient research which throws an unexpected light upon, and adds support to, the Darwinian theory of the evolution of species. The research concerned sea water. In M. Quinton's view sea water is the natural source from which, as Haeckel believes, those elementary bodies have their rise which in turn develop into every other species, human beings included. The environment in which the anatomical elements of living creatures exist is neither more nor less than a marine one. Our tissues and cells continue to exert their functions in a fluid the composition of which presents the closest resemblance to that of sea water. Hitherto the number of elements entering into the composition of a living body has been considered to be about 15. But the researches of M. Quinton have shown the existence of traces of at least some 14 other elements which are also found in sea water, such as copper, lead, silver, gold, and others. Further, if an animal be bled to exhaustion (*saigner à blanc*) and the place of the blood be supplied by sea water on the morrow the animal will have regained its strength and at the end of five days its recovery is complete. M. Quinton has injected into animals a quantity of sea water greater than their own body weight without any toxic effects, whereas an injection of pure water rapidly brings about death. Sea water then appears to be the true nutrient fluid of animals, their natural plasma, in fact. M. Perrier, who introduced M. Quinton's paper to the meeting, did not fail to point out to what recondite philosophical theories these facts might lead.

April 12th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The International Congress of School Hygiene.[1]

THE First International Congress of School Hygiene was held in Nuremberg from April 4th to 9th, under the honorary presidency of Prince Ludwig Ferdinand of Bavaria, M.D., Professor Griesbach of Strasburg acting as chairman. There was a very large attendance of medical men and educationists, the number of members being not less than 1130. They came not only from Germany but also from most countries of Europe, from Japan, and from the United States. Apart from the general meetings, the Congress was divided into 11 sections—namely: (1) School Buildings; (2) Hygiene of Residential Schools; (3) Methods of Hygienic Investigation in Schools; (4) Physiology and Psychology of Educational Work; (5) Instruction in Hygiene for Teachers and Pupils; (6) Games and Drill; (7) Medical Supervision of Schools; (8) Special Schools or Classes; (9) Hygiene of Children out of School; (10) Hygiene of the Teaching Profession; and (11) General Hygiene in its Relation to Schools. After the inaugural proceedings the first paper was read by Professor Hermann Cohn of Breslau, the well-known ophthalmic surgeon. He took for his subject the Hygiene of the Eyes and alluded to inquiries conducted by himself 40 years ago when he examined the eyes of 10,000 school children and found myopia to increase coincidently with over-exertion of the eyes in school so that the worst vision was to be found in the most advanced classes.—Of the foreign delegates Professor Johannessen (Christiania) read a report on School Hygiene in Norway. Some parts of Norway were so thinly populated that 10 per cent. of the children had to walk more than four kilometres (two and a half miles) to the nearest school. Nevertheless, medical officers were appointed to all Norwegian schools and medical women for the girls' schools. The teachers received instruction in hygiene from the medical officers. With regard to Christiania, the capital of Norway, he said that of the 19 municipal schools 17 were provided with bathing arrangements and 29 per cent. of the children received meals in the schools free of charge.—Dr. Le Gendre (Paris) read a paper on the Ill-health of Teachers in its Relation to the Pupils. He drew attention especially to tuberculosis and recommended that candidates for teaching appointments should undergo a careful medical examination so that those who were actually or possibly tuberculous might not be employed in teaching.—A great many other papers were read before the Congress, among which several were of medical interest. Professor Hueppe (Prague) spoke on Infectious Diseases in their Relation to Schools; Dr. Leubuscher (Meiningen) and Dr. Hartmann (Berlin) on the Duties of Medical Officers to Schools; Dr. James Kerr (London) on School Ventilation; Dr. Schmidt (Bonn) on Games and Physical Exercises; and Dr. Flachs on Dress Reform for Girls. It was announced that the next international congress on this subject would be held in London under the presidency of Sir Lauder Brunton.

Health of the German Navy.

A statistical report on the health of the navy during the period from April, 1899, to Sept. 30th, 1901, has recently been issued by the medical department of the Imperial Naval Office. The report states that the health of the naval forces has continued to improve from year to year since 1879. The proportion of men reported sick was 745 per 1000 in 1900 and 690 per 1000 in 1901; the daily number under medical care was 57·5 per 1000 in 1900 and 35 per 1000 in 1901. On an average each patient was under treatment for 17·8 days in 1899 and for 18·6 days in 1900, the respective numbers for some other navies being 15 1 days for the British, 20 4 for the Austrian, 11·1 for the American, and 9·4 for the French navy. The health conditions were very unsatisfactory on board the vessels of the East African squadron where malaria prevailed and in the German settlement at Kiao-Chau in China where an epidemic of enteric fever and dysentery had broken out. The mortality of the navy has somewhat increased of late years, the death-rate being 3·2 per 1000 during the period 1897–99 and 4·2 per 1000 during the above-mentioned period 1899–1901.

The Belitz Sanatorium for Tuberculosis.

The Berlin association for insurance against sickness under the workmen's insurance law (Landes-Versicherungs-Anstalt) has erected a large sanatorium for tuberculous patients at Belitz in the neighbourhood of Berlin. This sanatorium, which is a model of its kind, is situated in a forest district and is provided with every requisite for the treatment of the patients. It contains bedrooms, day-rooms, a dining hall, shelters for Liege-kur, and various departments for hydrotherapeutic treatment and other purposes. Although intended for patients belonging to the working class exclusively the arrangements are in every respect so good that they could hardly fail to be appreciated by patients of much higher social position. No charges have to be paid by the individuals undergoing treatment; all expenses are defrayed by the above-mentioned association, the only condition being that the disease is in a curable stage. The object aimed at in providing sanatorium treatment is to prevent working men and women from becoming permanent invalids, as in that case under the insurance laws the association would have to maintain them for the remainder of their lives. The sanatorium was opened on July 15th, 1902, for males and on August 11th for females and the report which was issued some weeks ago states that the male department was full on August 7th and the female department on August 21st. There are 180 beds for men and 72 for women. Of the patients admitted 70 per cent. were in the first stage, 25 per cent. were in the second stage, and 5 per cent. were in the third stage of pulmonary tuberculosis. In 11 per cent. pyrexia was present on the day of admission; in 14 per cent. tubercle bacilli were found. The results of the treatment were excellent: 94 per cent. were able to resume work and 40 per cent. did not show any symptoms of tuberculosis when they left the sanatorium. The patients increased in weight during their stay in the sanatorium, the average gain of weight being 6·6 kilogrammes for men and 5·3 kilogrammes for women. The treatment, apart from liberal nourishment, consisted chiefly of hydrotherapeutics and Liege-kur. No injections of tuberculin were given. It was observed that the improvement in health was generally much slower in women than in men. The average length of residence was 12 weeks. A number of the men left the sanatorium on finding that the loss of their earnings was a serious matter for those dependent on them. From the point of view of the institution this was unfortunate, because if these premature discharges could have been avoided the results would have been still better. It must be remembered that this sanatorium is not the only one carried on by the Workmen's Insurance Association. Its institutions include one for chronic, non-tuberculous diseases, also in Belitz; one for venereal diseases in Lichtenberg; one at Gutergotz for tuberculous patients in a more advanced stage; and some other smaller ones. As already mentioned, the object of these establishments, which have become a permanent feature in social hygiene, is to preserve as much as possible the insured workmen from becoming chronic invalids whose maintenance would be very costly.

April 12th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Renewal of Plague.

IN addition to the rinderpest, which has been absorbing all the energies of the Sanitary Department for the last nine months, human plague has now reappeared in Upper Egypt after so long an interval that it seems probable that it must have been reintroduced from abroad. The pilgrims now returning from Mecca are officially said to be free from plague and cholera and as yet no cause for this new outbreak has been found. History has again repeated itself, for it seems certain that the disease was kept concealed for some time before it was discovered by the sanitary officers. Barefaced concealment of infectious disease still continues in all the villages attacked, and cases are eventually found in houses which had been carefully searched a day or two [illegible] March 5th in some [illegible] *opposite the town of* [illegible] eaths which occurred prior to that date must have been due to plague. Altogether about 200 people have already been attacked and of these some 180 have died, the first known case being that of a man who died in his village five days after returning from Assiout where he had been called as a witness in the law courts. *The high mortality is due to the fact* that *the disease is* taking the pneumonic form, eight persons out of a family of 11 having died in one house and four deaths occurred in another household of five people. Cases of plague have also occurred in the little town of Tahta where for some days there has been a marked mortality among the rats. Additional reports have been received from some villages in Keneh province on both sides of the Nile; from one of these a man accompanied by his wife and three sisters went across the Nile to attend a relative's funeral. Three days later the man, his wife, two of these sisters, and two other sisters had all died from plague. Since then other cases [illegible] n confined [illegible] Major O. [illegible] the neces- [illegible] he disease but at this time of the year it is quite certain that it will spread in spite of all efforts. It is difficult to keep patience with the natives who obstruct legitimate and tactfully considered sanitary precautions, especially when dealing with villagers who suffered severely from plague only a year ago. Major Garner, for instance, suspected the existence of plague at the village of Naknak but on inspection could find no cases there. Yet on the following day the wife of the sheikh of the village died and on the next day the niece of the sheikh and two other people were found plague-stricken in the village. There can be no doubt that these cases were purposely hidden during the house-to-house inspection and nothing short of severe punishment will prevent similar occurrences in other places. It will take many a long year to change the habits of the Egyptian rustics who do not in the least believe in the necessity of cleanliness and disinfection, who imagine that all illnesses come from an evil spirit, and that the Government officials are all their hereditary enemies. If the many problems of endemic disease are ever to be attacked seriously in Egypt the staff of English inspectors must be considerably increased. At present all the time of the staff is taken up in combating epidemics and, unfortunately, for some years to come the supply of native medical men will not equal the demand. A further case of plague has now been reported from Suez in a man who had just returned from Port Said.

Kasr-el-Ainy Hospital.

This hospital and the medical school in connexion with it are progressing satisfactorily every year. Electric lighting is now being provided for the wards and the administrative offices and a new laundry has been built which will be worked by electric power. The in-patients have increased in number to 1000 more than in previous years and the out-patients number 66,000 annually, of whom 35,000 are new cases. The entry of students last October was 36, being more than at any time since the old days when youths were brought by force to the Government schools. A micro-photograph room has been opened and also an additional room for the physiological laboratory. Mr. G. L. Crimp has been temporarily engaged for pathological work during the absence of Dr. W. St. Clair Symmers at the serum institute for cattle plague, and Dr. G. Elliot Smith has also been given an English assistant for anthropological work.

Obituary Notice.

Captain H. E. Haymes, R.A.M.C., of the Soudan Civil Administration, died in the Soudan on March 15th. His death is not only deeply regretted by his many friends but it is a very serious loss to the Government. After a distinguished career at St. Thomas's Hospital he took resident appointments at the Royal Berkshire Hospital, Reading, and the Eastern Counties Asylum, Colchester, and soon after entering the Royal Army Medical Corps he applied for service in the Egyptian army. He first came to the front while in surgical charge of the wounded dervishes after the capture of the Khalifa at the end of 1899 and for his services on that occasion he was admitted to the Order of St. John of Jerusalem. In November, 1900, he accompanied Lieutenant-Colonel Sparkes, C.M.G., on a tour, which eventually lasted 18 months, in the Bahr el Gazzal province, and they travelled together all through the Niam-niam country, where Haymes's skill in surgical operations spread far and wide and did much to pacify the wild tribes to whom England's power was unknown. His medical and sanitary work were alike excellent and he had in addition the rare gift of administrative ability which marked him out very strongly for future employment as head of a province. He was a very good all-round sportsman and a splendid big game shot. He also went with Major Hunter on a punitive expedition in the Rumbek district, where he was wounded in the hand by a spear. He was specially decorated by H.H. the Khedive for his valuable services and then returned to Cairo to repair his own health after many attacks of malaria. Soon disdaining the delights of polo and smart society he volunteered to return to the Bahr el Gazzal where he was given both administrative and medical duties and while serving there he was again selected to accompany a small military patrol. The patrol was fired at by some ignorant villlagers and unfortunately Haymes was slightly wounded in the head. The climate is a very bad one for surgical injuries; his previous hardships had doubtless weakened his constitution and pyæmia including a septic abscess of the lung resulted, causing death in 13 days. He was universally beloved by his fellow officers and friends and he won the hearts of all the natives by his exceptional qualities of just, upright, brave, straightforward common sense.

Cairo, April 3rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A Bill to Remodel the Medical Department of the United States Army.

A BILL has been introduced recently into the Senate and House of Representatives of the United States framed with the view of bringing about important changes in the Army Medical Service. According to the Surgeon-General of the United States Army the Medical Department at present suffers from three serious defects of organisation which handicap its efficiency in time of peace and render impossible any efficient expansion in *time of* war. *These* are: a commissioned *personnel* entirely inadequate to perform the medical service of the army even in time of peace; *insufficient* inducement in the way of pay and promotion to attract the most desirable class of young physicians to enter the corps; and no satisfactory means of expansion *to meet* war conditions and special needs in time of peace. The only means of expansion heretofore existing, the employment of contract surgeons to supplement the insufficient commissioned *personnel*, has always been wasteful and unsatisfactory and has now become absolutely unpractical because of the recent decision that the contract surgeon not being an officer obedience to his orders cannot be enforced even in the case of the enlisted men of the hospital corps. The organisations necessary to remove these defects are briefly as follows. The medical department to consist of medical corps and medical reserve corps. Medical corps.—1. Size: (*a*) sufficient to form an adequate nucleus in time of war, and (*b*) sufficient to do all ordinary duty in time of peace. 2. Grades: (*a*) to offer sufficient emoluments to induce efficient men to enter the corps; (*b*) to officer properly the war nucleus; and (*c*) to officer properly and to administer in time of peace. Medical reserve corps to be drawn from medical men in civil life.—1. Size: (*a*) to meet unusual demands in time of peace, epidemics, care of troops at small stations, examination of recruits at unimportant places, &c.; (*b*) to increase medical department to proper size to meet demands in insurrections and small wars where increase in upper (administrative) grades is not necessary and where volunteer troops are not called out. 2. Grades: to have commissioned grade in order to meet adequately requirements of military service.

The Sanitary Condition of the Isthmus of Panama.

Dr. J. O. Perry of the United States Public Health and Marine Hospital Service has been at Colon and the Isthmus of Panama by the command of President Roosevelt, making investigations into the sanitary condition of the canal. Dr. Perry has submitted an exhaustive preliminary report to the Surgeon General to the Public Health and Marine Hospital Service. The writer finds malarial fevers in all forms the chief bane of the locality, but yellow fever, tuberculosis, and rheumatism are more or less prevalent. He finds the sanitary conditions in Colon and Panama extremely bad and along the railway road the state of affairs in this respect is even worse. The death-rate of Colon is high. Statistics compiled give an annual death-rate of 47 per 1000, but taking into consideration that these are probably incomplete he thinks that the mortality is not less than 50 per 1000. He considers that the natives are not so immune as is generally thought to be the case, although, of course, they have acquired a considerable degree of immunity. The rainy season at Colon and in the immediate vicinity lasts from May to January, the rainfall during that period averaging about 125 inches, which is twice the precipitation at Panama. Along the line of railroad between the two cities are 18 villages, with a population of about 15,000, almost exclusively negroes and Chinese. The sanitary condition of these places is wretched in the extreme. As to what extent the prevailing diseases can be diminished or prevented by proper sanitary equipment and regulations Dr. Perry says: "Having shown that 75 per cent. of the diseases are malarial; yellow fever exists and will increase upon introduction of new material; that dysentery, tuberculosis, and rheumatism are common, I think that a conservative estimate would be that 80 per cent. or even more of these diseases could be prevented." 75 per cent of the population of Colon consists of Jamaican or other negroes and Dr. Perry is of the opinion that to make it a clean city will necessitate the destruction of all the shanties which they now inhabit and their replacement by dwellings built on good sanitary principles. The conditions are much the same in Panama, which, Dr. Perry says, can be made a healthy tropical city by the introduction of a modern sewerage system and a good water-supply.

Paper Money as a Means of Carrying Infectious Germs.

Dr. Thomas Darlington, health commissioner of the city of New York, has pointed out the dangers liable to result from the use of coins and of dirty paper money, based upon the investigations of Dr. William H. Park, head of the Bureau of Research in the Department. The report made by Dr. Park was to the effect that experiments upon coins demonstrated that the metals produced a deleterious effect upon bacteria, so that within 48 hours they were usually free from disease bacteria. He further reported that the investigations so far have established the fact that bacteria are not killed by any substance in paper money but remain alive until time and drying destroy them. No actual disease bacteria have as yet been demonstrated. The report is only preliminary; experiments are still going on and will be continued for some time.

April 2nd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Bubonic Plague.

BUBONIC plague has broken out again in Queensland. Five cases have been reported from Brisbane. Three cases were unofficially stated to have occurred at Cairns but on further investigation one proved not to be plague. Dr. B. B Ham, the health commissioner, has had to object to irresponsible statements being made to the press as to suspicious cases of illness. The Board of Public Health in Victoria has forwarded a circular to all the municipalities in that State requesting that steps should be taken to destroy all rats as a precaution against plague. During the last quarter of 1903 29,000 rats were destroyed, but only about six municipal bodies have concerned themselves in the matter.

Typhoid Fever in Victoria.

Typhoid fever has increased in prevalence in Victoria this season. The returns for the fortnight ending Feb. 27th showed 225 cases, with ten deaths, as against 138 cases during the corresponding period of 1903. The increase was especially marked in the Bendigo district. The Board of Health is inquiring into the condition of the cases in the suburbs of Melbourne, especially as to their relations to milk-supply, and a report is being prepared. 75 cases of typhoid fever are under treatment at the Melbourne Hospital.

Prevention and Treatment of Tuberculosis.

The Victorian Society for the Prevention of Tuberculosis has prepared a leaflet dealing with the proper disinfection of houses after their occupation by consumptives. It recommends the burning of wearing apparel, pillows, and mattresses, the repapering of rooms and ceilings, and the washing of floors and furniture with disinfectants. The leaflet has been forwarded to the press with a request for publication and also to municipal councils. The latter have been asked to instruct their health officers to insist on proper disinfection and ventilation of houses. The committee of the Austin Hospital has called for tenders for the erection of the Kronheimer wing for consumptives but the residents in the neighbourhood are still agitating against its erection and the Premier declines to give a maintenance grant to the institution. A meeting was recently held in Melbourne of the subscribers to the Victorian Sanatorium for Consumptives, which has recently been incorporated under the Hospitals and Charities Act, to adopt by-laws and to appoint staffs for the management of the sanatorium. The objects of the institution were stated to be "the prevention and cure of tuberculosis (*a*) by treating persons who are labouring under such an incipient form of disease as to afford a reasonable hope of their obtaining benefit from a temporary residence in a suitable climate; (*b*) by treating persons who, being convalescent, require further medical treatment and change of air to re-establish their health; (*c*) by treating persons who may be in such other conditions as the institution in any general meeting may consider it advisable to treat; and (*d*) by such wider or other means as the institution may think fit to adopt." Under By law 17 power was given to the committee of management "to appoint and dismiss medical and other officers, whether honorary or otherwise." An amendment that the honorary medical officers might be elected by the subscribers was rejected. The following were appointed honorary medical officers: Consulting physician: Mr. D. Turner. Medical examiners: Melbourne, Dr S Bird, Dr. R H. Strong, and Dr. Turner; Echuca, Dr. R. Bindon Stoney; Eaglehawk, Dr. B. S. Cowen; Bendigo, Mr. O. Burke Gaffney; Warrnambool, Dr. M'Knight.

Friendly Societies' Institutes and the Medical Profession.

Reference has previously been made to differences existing between the Balmain United Friendly Societies Dispensary and the New South Wales branch of the British Medical Association. The dispensary used to have four medical officers to whom the sum of £1320 per annum was paid in the following manner. Each medical officer was paid a monthly salary at the rate of £150 per annum and the remaining £720 were divided into 12 parts of £60, allotted to the officers according to the number of prescriptions issued by each. The medical officers were allowed a guinea for confinements and the right of private practice. The dispensary has 3500 members, and the amounts paid to the surgeons averaged about 7*s*. 6*d*. a member. The New South Wales branch of the British Medical Association thought that the payment was too little and at its instigation the four medical officers demanded payment *per capita* at the rate of 16*s*. per member per annum, practically the same rates as those received by the local lodge surgeons before the dispensary was established. The dispensary board of managers declined to adopt the system and two of its four medical officers resigned. The British Medical Association Council then declared the dispensary "inimical to the interests of the medical profession" in the terms of No. 36 of its Articles of hold the position of medical officer to the dispensary, or meet the medical officers in consultation. The dispensary board then decided to appoint three medical officers at a fixed salary of £450 per annum each, and advertised the positions. A number of applications were received and Dr. P. J. Kelly, Dr. Ellen Wood, and Dr. M J. Cortis were appointed. The two first named were previously medical officers to the dispensary. Dr. Kelly was also a candidate for the position of paid medical officer to the Balmain Hospital and when the election by the hospital committee came on it was pointed out that if Dr. Kelly were appointed the honorary medical staff of the hospital would not meet him or work with him. The committee appointed Dr. Kelly.—In Bendigo, Victoria, a somewhat similar difficulty occurred. The United Friendly Societies' Institute had some difference with one of its medical officers who resigned. The Victorian Medical Defence Association issued a circular to the profession pointing out the conditions of the contract between the institute and its medical officers and warning medical men not to apply for the position on much the same grounds as those taken by the British Medical Association in New South Wales as to the Balmain Dispensary, chiefly that the annual salary, £450 per annum, to each of the two medical officers for attending to 2362 members and their families was too low and much below the *per capita* rate ruling in the district. The Medical Defence Association had previously passed a resolution to the following effect:—

> That it is contrary to the interests of the medical profession that medical men should accept office in friendly societies' institutes where the aggregate salary averages per member less than the rate paid in the district.

The medical men practising in Bendigo held a meeting and passed the following resolution:—

> That we agree not to meet in consultation the medical officers of the Bendigo Medical Institute so long as the rule (No. 7 in the resolutions of the Medical Defence Association) bearing on the salaries of their officers is not complied with. (Rule 7 is the resolution above quoted.)

22 medical men applied for the position at Bendigo, but after the issue of the circular of the Medical Defence Association five of them withdrew. Dr. T. O. F. Alsop was appointed.

March 4th.

Obituary.

JOSEPH MAY, F.R C.S ENG., L.S.A., J P.,

CONSULTING SURGEON TO THE ROYAL ALBERT HOSPITAL, DEVONPORT.

Mr. Joseph May died at his residence, 1, Nelson-gardens, Stoke, Devonport, on April 10th, in his ninety-seventh year. Mr. May, who was born in Devonport, was articled to Mr. Tripe, a surgeon of Devonport, and received his medical education at St Bartholomew's Hospital and the Aldersgate-street School of Medicine. In 1830 he took the qualifications of M.R.C.S Eng. and L.S.A. Mr. May then studied his profession in Paris and in 1831 offered his services to the Polish army, then fighting against Russia and was appointed chief surgeon to the Nyazdowa Hospital. He then joined the army at Warsaw and was present at the siege of that town After its surrender Mr. May returned to England, having been awarded the decoration of the Cross of the Polish Order of Stanislaus. In 1832 he commenced practice at Devonport and was appointed honorary surgeon to the Devonport and Stonehouse Public Dispensary which was eventually merged into the Royal Albert Hospital. Mr. May always took a prominent part in municipal matters; he had been an alderman for many years and four times filled the mayoral chair. He was presented with a magnificent candelabra and his portrait in oils as a recognition of his devoted labours in connexion with the opening of the Plymouth Devonport, and South-Western Junction Railway in 1876 Mr. May was for 20 years on the School Board and for 12 years occupied the position of chairman. He took a great interest in all matters connected with education and was for many years vice-chairman of the Devonport Girls' High School. He was a justice of the peace. In 1899 he was presented with the freedom of the borough of Devonport. He leaves a widow and two sons, both members of the medical profession, one daughters. Mr. May will be greatly missed in Devonport, where he was held in the very highest esteem, and by his death the medical profession loses a member of whom it may well be said that he was in every sense of the words a credit and an ornament.

WALTER WINTER WALTER, M.R.C.S. ENG., L.S.A.

Mr. Walter Winter Walter of Stoke-sub-Hambden, Somerset, died on April 1st in his seventy-ninth year. The deceased, who took the qualifications of M.R C.S. Eng. and L.S.A. in 1846 and 1848 respectively, had practised for many years at Stoke. He was a former president of the West Somerset branch of the British Medical Association. Mr. Walter in his younger days was an active member of the Somerset Archæological Society and his collection of antiquities, which was one of the finest in the West of England, was presented by him a few years ago to the County Museum at Taunton where they are known as the "Walter Collection." The deceased, whose wife predeceased him by a few days, was buried on April 5th in the churchyard of Stoke. He leaves a son who is a member of the medical profession.

DANIEL MOUNCEY ATKINSON, L R C.P., L R.C S EDIN., L.F.P.S. GLASG.

Mr. D. M. Atkinson, who died recently in Glasgow, was well known among the younger practitioners of that city and the position he had already attained led his many friends to consider his prospects as of the brightest. He was born in Yorkshire, being the son of a medical man in practice at Ferry Bridge near Pontefract. He received his medical education in Glasgow at Anderson's College and at St. Mungo's College, the medical school in connexion with the Royal Infirmary, where he gained medals in the classes of clinical medicine and operative surgery. Not long after becoming qualified in 1895 he resolved to settle in Glasgow and for some years he had been assistant to the professor of clinical medicine in St. Mungo's College. Mr. Atkinson, who was 49 years of age at the time of his death, possessed a considerable collection of coins and jewellery which had descended to him as a family heritage.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated.—

PART I.

Biology—G. F. C. Harvey, London Hospital, and E. A. Mordaunt,

E A. Mordaunt and
nds, Glasgow; C. S.
Free Hospital.
er, Royal Free Hos-

PART II.

Anatomy.—I R Fearn and J. W. Featherstone, Guy's Hospital, T S Harrison, Manchester; R. J. W. McKane and A. W. C. Miller, Leeds, F B O Dowd, Birmingham, H. V. White, Manchester, F H P Wills, St. Mary's Hospital; and R. P. Wylde, Manchester.

Physiology—A C Dickson and I R. Fearn, Guy's Hospital; J. C. Fletcher, Royal Free Hospital, J. W. Featherstone, Guy's Hospital; W. J. G Gayton, London Hospital, T. S. Harrison, Manchester, A W. C. Miller, Leeds; F. B O Dowd, Birmingham; H. V. White, Manchester, and F. H. P. Wills, St. Mary's Hospital.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the recent quarterly examinations of the Scottish Conjoint Medical Board, held in Edinburgh, the following candidates were successful:—

First Examination—Zerk Daniel
Andrew Johnstone, Edinburgh
Wigan, Charles Kinsley Carroll
Ireland (with distinction); Ma
Daniel Johannes Joubert, Stelle
Rosscarberry, Cornelius Alexa
Edward John Lumsden, Cou
Ashbourne; Easton Spence Shi
du Toit Malan, Cape Colony.

Second Examination.—Archib[illegible] Kirkcaldy (with distinction); Edward Albert [illegible] [illegible]nction); Harold Hubert Babington, Ire[illegible] Carnbee (with distinction); Ronald W[illegible] Wilfrid Metcalfe Chambers, Knock, [illegible] Patrick O'Connell, Saugor, India; Joseph Benjamin Norman Raphael-Tom, Trinidad; Howard Douglas Stewart, London; Krishnaji Waman Dani, Poona; John Theodore Anderson, Victoria; Douglas Llewellyn George Radford, Leith; Herbert Moncrieff Sturrock, Edinburgh; Herbert Charles Orrin, Colchester; Thomas Wrenn Faulkner, Cooma; [illegible] Narayan Ghosh, Lucknow.

Third Examination. [illegible] Edinburgh (with distinction); James [illegible] distinction); Henry Traill Simpson, Le[illegible] [illegible]rge Augustus Stewart Hamilton, Dublin [illegible] [illegible]egge, Dundee; Henry Albert Pascoe, Ne[illegible] [illegible]omas McLaren Galloway, Sinclairtow[illegible] [illegible]am Fleming, County Durham; and Jo[illegible]

Final Examination [illegible] *the three Coöperating Authorities*).—Alford Rogers, Burry Port; Andrew Sergeant McNeil, Preston; John Alexander Tolmie, Ontario; Marian Theresa Pool, London; John Clegg Pickup, Burnley; William Douglas Yuille, Melbourne; Harry Andrew Foy, Cawnpore; Phirozshaw Cooverji Bharucha, India; Edmund O'Shaughnessy, co. Cork; Abdul Hakim Khan, India; Cunamal Santdas Thadani, Hyderabad; John Cretin, Mauritius; Dora Mann, Eisenberg; Edwin Nelson Jan, Ceylon; Chauncey Eugene Coke, Ontario; Herbert James George, Jamaica; William Thomas Clark, Ontario; George William Armstrong, Wales; Arthur Charles Lodge La Frenais, Madras; and David John Lewis, Newcastle.

UNIVERSITY OF GLASGOW.—The following have passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., Botany; Z., Zoology; P., Physics; and C., Chemistry):—

Archibald Aitchison (Z.), John Andrew Aitken (P.), William Allan (C.), David Anderson (Z.), William Anderson (B., P.), Thomas Archibald (Z., C.), James Currie Auchencloss (B., Z., P.), William Barr (Z.), Frank Beaton (B.), Charles Bennett (Z., C.), Robert Inglis Binning (B., P.), John Blakely (Z.), John Lindsay Boyd (Z.,* C.), William Brown, M.A. (B.), William Barrie Brownlie (Z., C.), David Young Buchanan (Z.), Murdo Buchanan (Z.), Hector Mackay Calder (P.), John Cameron (Z., P.), James Carrick (Z., C.), Donald James Clark (Z.), John Humphrey James Victor Coats (B.), James Cook (Partick), (Z., C.), John Cruickshank (Z., C.*), Walter Dawson (P.,* C.), James Cowie Dick (B.), William Hunter Duncan (B.), James Kirkwood Dunlop (P.,* C.), Allan Dunsmuir (C.), Thomas Loudon Fleming (B.), Thomas Forsyth (B.), William Leonard Forsyth (Z., C.), John Fotheringham (Z.), Berkeley Gale (C.*), David Gibson (Z., C.), Walter Gilmour (Z., C.), Hugh MacVicar Gossman (B.,* P.), Alexander Thomas Arthur Gourlay (B., P.,* C.), Edward O'Driscoll Graham (P.), Thomas Edmondstone Gray (Z.,* C.), William Cooper Gunn (P.), Josiah Stranaghan Harbinson (B., Z., P.,* C.), Stephen John Henry (Z., C.), James Hall Hislop (Z., P.), William Alexander Hislop (P., C.), Archibald Hogg (B.,* C.), Benjamin Hutchison (Z.,* C.), Alexander Mills Kennedy (Z., C.), Thomas Joseph Kirk (Z.), John Lang (Z.), William Leitch (B., Z., P., C.), Daniel Conway M'Ardle (B., C.), Peter Cunningham M'Arthur, M.A. (B.*), Frank Crombie Macaulay (Z.), Hugh M'Callum (Z., P.), Ro[illegible] Macphail Macdonald (Z.), Alexander [illegible] Joseph Bogue Mackay (B., P., C.), [illegible] Francis William Mackichan (B., P.*), William Campbell Mackie (Z., C.), William Edward M'Lelland (C.), James Walter M'Leod (Z., C.), James M'Millan M'Millan (Z., P.,* C.), John MacMillan (B., P.), Peter Russell M'Naught (Z.,* C.), Donald Irvine M'Naughtan (B., P., C.), Allan M'Pherson (Z., P.), William Aubrey Layard Marriott (Z., C.), Frank Needham Marsh (Z., C.), Horatio Matthews (C.), Kenneth Chisholm Middlemiss (Z., C.), Thomas Miller (Z.), Robert M'Kenzie Morison, M.A. (B.,* Z., C.), Hugh Morton (C.), James Muir (Z., P., C.), Robert Charles Muir (P.), William Aikman Muir (Z., P.*), Archibald Campbell Munro (Z.,* C.), Arthur Alexander Murison (P.), Charles Sutherland M'Kay Murison (B., C.), Archibald Naismith (P., C.), Watson Noble (Z., C.), Albert Rutherford Paterson, (Z.,* C.), Adam Patrick (B., Z.), Ralph Montgomery Fullarton Picken (Z.*), David Purdie (Z., C.), Murray Purvis (Z., C.), Edward Quigley (Z., P.*), Richard Rae (Z.), Nicol M'Nicoll Rankin (B., Z.), Thomas [illegible], P.*), George Waugh Scott (P., C.), Allan [illegible] Alexander Sewell (Z., C.), James Brown [illegible] C.), Lawrence Storey (C.), [illegible] [illegible]avid Taylor (Z., C.), Walter Telfer (P., [illegible] (B., P., C.), John Shedden Thomson ([illegible] [illegible]r (Z., C.), William Samuel Waterhous[illegible] Thomas Charles Dalrymple Watt (C.), [illegible] (Z., P.*), David M'Gruther Wilson (Z., C.), Hugh Mundle Wilson (B., P.,* C.), and William Alexander Wilson (B., C.).

Women.—Martha Maclean Buchan (P., C.), Margaret Baird Sproul Darroch (B., Z.), Mabel Foley (P.,* C.), Margaret Gardner Forrest (B.,* P., C.), Jeanie Walker Jones (P., C.), Annie M'Crorie (B.), Janet Annie Mac ea (Z.), Flora Morrison (P.), Jeannie Peden Rose (B., Z.), Winifred Margaret Ross (P.), Jessie Capie Russell (P.,* C.), and Jeanie Hinshaw Stewart (P.,* C.).

The following have passed the second professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (A., Anatomy; P., Physiology; and M., Materia Medica and Therapeutics):—

George Victor Anderson (A., M.), James Montgomery Anderson (M.), Andrew Hamilton Arnott (P., M.), John Bain, M.A. (A.), Thomas Barbour, B.Sc. (A., P.), Charles Burns (P.), William Archibald Campbell (A., P., M.), Donald Livingston Carmichael (P., M.), Henry Howard Christie (A., P., M.), Donald Clark (M.), John Sawers Clark, M.A. (A., P.), James Coutts (A., P., M.), Andrew Donaldson Cowan (A., M.), Thomas Lawson Craig (A., P.), Arthur Muir Crawford (A., P., M.), Weir Burns C[illegible] (A., P[illegible] Harold Windley Dempster (P., M.), Allan [illegible] Richard John Driscoll (M.), James Du[illegible] Eaton (A., P.), Thomas Henderson Forr[illegible] Georgeson (P.), William Gilbert (A., P., [illegible] (A.), Arnold Harris Gray (A., P.), Jo[illegible] (M.), Robert Neil Guthrie (A., P., M.). [illegible] P.), William Towers Hardie (A.) Rober[illegible] Lawrence Hislop (M.), David Guthrie [illegible] Harry Stewart Hutchison (M.), Arnold [illegible] Percy James Kelly (A.), John Keys (A., P.), James Dunlop Kidd (A., P.), Robert Wright Leckie (A.), Alexander Leggat (A.), Alexander M'Call (P.), John M'Cartney (M.), David MacDonald (A., P., M.), James M'Farlane (A., P., M.), John Henry M'Kay (A., P., M.), Thomas Cooper Mackenzie (P.), William Ferguson Mackenzie (A., P., M.), William Macleod (A.), Norman Smith MacNaughtan (A.), Alister Argyle Campbell M'Neill (A., P.), Charles James Colquhoun Macquarie (A., P.,* M.), William Hislop Manson, M.A. (M.) [illegible] Marshall (A., P.), Robert May (A.), John Miller (A., P., M.), [illegible] Peter Mitchell, M.A. (A.,* P.*); Hugh Walker Mon[illegible] [illegible]rick Joseph O'Hare (A.), John Oswald (P.), James Hogg Paul (A., P.), Arthur Geoghegan Paxton (P.), John Reid (M.), Frederick Gordon Robertson (A., P., M.), John Cooper Russell, M.A. (M.), William James Rutherfurd (A., P.,* M.), Alfred Cecil Sharp (A.,* P.*), John Sharp (A., P., M.), James Charles Donaldson Simpson (P., M.), Robert Alexander Slater (A.), William Smellie (A., P.), Thomas Baillie Smith (A., P., M.), James Stevenson (A., P.), John Stevenson (A., P.), Arthur Anderson Stewart (A.), David Laurence Alexander Tate (A.,* P.,* M.*), Charles Samson Thomson (A., P., M.), Martin Turnbull (P.), Alexander MacMillan Watson (A.), James Kennedy Welsh (A., P., M.), David John Williams (M.), George Haswell Wilson (A., P., M.), Moses Youdelevitz (A., P.), and John Young (Mount Vernon), (A.).

Women.—Jean [illegible] Andrew (A., P.), Rose Isobel Hudson (A., P., M.), [illegible]s (A.), Agnes Picken, M.A. (A., P[illegible] Reid (A., M.), Vera Dagmar Rei[illegible] (P., M.).

Old Regulations.—Mr. Robert Stewart M'K[illegible], M.A., has passed the second professional examination (Anatomy and *Physiology) for the degrees of M.B. and C.M.

The following have passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (P., Pathology; and M., Medical Jurisprudence and Public Health):—

George Allison Allan (P.), William Smith Allan (P., M.), Andrew Allison (P., M.), Andrew Woodroffe Anderson (M.), James Henderson Baird, B.A. (P., M.), Hugh Barr (P., M.), George Duncan Morrison Beaton (P., M.), John Miller Hopkins Caldwell (M.), Thomas Murdoch Campbell, M.A. (P., M.), Charles Game Angus Chislett (M.), Robert Wilson Dale, M.A. (P., M.), Robert Scott Dewar, M.A. (P., M.), Walter Duffy, M.A. (P., M.), John Shaw Dunn, M.A. (P.*), Eric John Dyke (P., M.), Hamilton William Dyke (P., M.), James Fairley (P., M.), Harry Prescot Fairlie (P., M.), Alexander Burns Ferguson (P., M.), George Garry (M.), James Gemmell (P.), Joseph Glaister (P., M.*), Alexander Graham, B.Sc. (P., M.), William Grier (P.*), Charles Francis Dyer Hammond (M.), James Duncan Hart (P.), Frank Hauxwell (P.), James Waugh Hay (P., M.*), Ralph Vincent Howell (M.), Alexander Hunter (M.), James Hunter (P.), William Boyd Jack (P., M.), George Notman Kirkwood (P.), William Love Kirkwood (P., M.), George Hugh Logan (P., M.), Peter Lowe, M.A., B.Sc. (P., M.*), John Bertram M'Cabe (P.), Thomas M'Cosh (P.), Walter George Macdonald, M.A. (P., M.), Duncan M'Ewan (P.), Hugh Allan Macewen (P., M.), James Denniston Macfie (P., M.), John Macintyre (M.), Ronald Mackinnon (M.), Roderick MacLeod (P.), Matthew Thompson Drummond M'Murrich (P., M.), Hugh MacNaught (P.), Peter Maguire (P., M.), William Main (P., M.), John Moffatt (P., M.), William Struthers Moore (P., M.*), Henry Joseph Milligan (M.), David Robertson Mitchell (P.), John Dunn Nisbet (M.), John Pearson (P.), Henry Sherwood Ranken (P., M.), Cunison Deans Rankin (P., M.), Thomas Hood Rankin (M.), Thomas Thomson Rankin (P.), James Mill Renton (P., M.*), Arthur Robertson (P., M.), William Rolland (P.*), Campbell Ross (P.), John Macdonald Ross (P.), Alexander Cappie Russell (P., M.*), Edward Louis Augustin Sieger (M.), William F[illegible] Sieger (P.), James Alexander Somerville (M.), Thomas [illegible] Alexander Stuart (P., M.*), John Taylor (P[illegible] [illegible]*), William Lind Walker, M.A. (P.), Alexa[illegible] (M.), and George Young (P., M.).

Women.—Bethia Shanks Alexander (M.), Jeannie Thomson Clark (P.), Mary Theresa Gallagher (P., M.), Elizabeth Maud M'Vail (P.), Charlotte Reid Park (M.), and Mary Spence (M.).

* Passed with distinction in the subjects indicated.

UNIVERSITY OF ABERDEEN.—The following degrees and diploma have been conferred:—

Honorary Degree of Doctor of Laws (LL.D.).—Charles James Cullingworth, M.D., St. Thomas's Hospital, London.

Degree of Doctor of Science (D.Sc.).—Andrew Norman Meldrum, B.Sc.

Degree of Bachelor of Science (B.Sc.).—John Foubister, M.A., Orkney; William Wilson Fyvie Aberdeen; John Gray, M.A., Forgue; Ian Quiller Orchardson, London; and William Slessor Simpson, M.A., Newburgh.

Degree of Doct[illegible] [illegible]ott Hoggs, M.B., Ch.B., Brigh[illegible] [illegible]don; *Robert Don[illegible] [illegible]adell Macdonald, M[illegible] and Alexander R[illegible]).

* [illegible]

Degrees of Bachelor of Medicine (M.B.) and Bachel[illegible] *Surgery (Ch.B.).—With First-class Honours:* †James Clark, Sorn, Ayrshire

With Second-class Honours: Francis Hérnaiman Johnson, Aberdeen, … *Ordinary Degrees:* … nderson, Gamrie, … e; Alexander Dyce … Davidson, London; … Farquhar, M.A., … Alexander Gibb, … M.A., Drumlithie, … Aberdeen; John … M.A., Aberdeen; … Kennedy, M.A., … West Bromwich; … Orkney; Herbert … William Alexander … ood, Peterhead.

D … *Master in Surgery* … Cardno, M.A., … Fraserburgh …

D … Aberd., Cabrach.

MEDICAL MAGISTRATE.—Mr. J. E. Panton, M.D. Durh., M.R.C.S. Eng., has been appointed a justice of the peace for Bolton.

UNIVERSITY OF OXFORD.—The Vice-Chancellor has nominated Mr. Arthur Thomson, M.A., Exeter College, Professor of Human Anatomy, to act during the absence of the Regius Professor of Medicine as his deputy.—The Board of the Faculty of Medicine gives notice that it has approved the examination in Group C (3) of the Final Pass School as an examination in physics.

CHILDREN'S COUNTRY HOLIDAY FUND.—The annual meeting of the supporters of this fund will be held at the Hôtel Métropole, London, on Thursday, April 28th, at 3.30 in the afternoon. H.R.H. the Duchess of Albany has promised to preside. The speakers will be Mrs. E. Garrett Anderson, M.D., Mr. William Crooks, the Lord Bishop of Kensington, Mr. W. Pett Ridge, M.P., and Mr. I. Zangwill.

DONATIONS AND BEQUESTS.—Mr. J. Earley Cook has by his will left legacies in reversion after Mrs. Cook's death or remarriage to the Metropolitan Convalescent Institution, £1000; to the London Hospital, £2000, with a present annuity of £60; to St. Thomas's Hospital, £200; to Bolingbroke Hospital, £100; to the Earlswood Asylum, £500; to All Saints' Convalescent Hospital, Eastbourne, £300; to the Seaside Convalescent Hospital, Seaford, £200; to the Deaf and Dumb Asylum, Old Kent-road, £200; to the Indigent Blind School, Southwark, £200; and to the Margate Infirmary, £200.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The election of examiners will be held on Tuesday, May 3rd, as follows:—Two examiners in anatomy, four in surgery, two in physiology and histology, one examiner in pathology and bacteriology, one in pathology, one in midwifery and gynæcology, one in biology, two examiners in ophthalmology, one examiner in sanitary law and vital statistics, two examiners in chemistry and physics, two in dental surgery and pathology, and two in mechanical dentistry. Candidates are requested to lodge their applications in writing with the Registrar, at the College, on or before Tuesday, April 26th, at 10 A.M.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The spring meeting of the South-Eastern division of the Medico-Psychological Association will be held at the West Ham Borough Asylum Goodmayes, Ilford, Essex, on April 29th. An inspection of the asylum and grounds will be made from 12 noon to 1.30 P.M., when the members of the association will take lunch with Dr. D. Hunter, the medical superintendent. During the afternoon Dr. F. W. Mott will give a lantern demonstration on the Significance of the Convolutional Pattern of the Human Brain, and Dr. D. G. Thomson will read a paper on the Nursing Bill from the Mental Nursing Point of View. Members will subsequently dine at the Café Monico, Piccadilly-circus, London, W. Dinner tickets, price 5*s.* each, can be obtained from the honorary secretary, Herts County Asylum, Hill End, St. Albans.

DEATH OF A CENTENARIAN.—It is announced that Mr. Alexander Alves, who died at Spalding on April 10th, was born in Edinburgh on Oct. 5th, 1803, and was therefore in his 101st year. He left Scotland when 23 years of age and for some years lived at Walthamstow, near London. He afterwards was employed as a bailiff and head gardener at Chislehurst in Kent until he was nearly 80 years of age.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. Sidney C. Lawrence, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H., lecturer and examiner of the St. John Ambulance Association and honorary surgeon to the Earls Barton division of that Association, has been presented with a pair of opera glasses as some acknowledgment of the valuable assistance which he has given to the cause of first aid and nursing at Earls Barton during the past seven years.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—An entertainment has been arranged by Mrs. Edgar Speyer and Mrs. Carl Derenburg in aid of the nervous diseases research fund of the National Hospital for the Paralysed and Epileptic and will be given at the Æolian Hall, New Bond-street, London, W., on Friday, April 29th, at 9 P.M. The programme will consist of the Bach sonata for violin and pianoforte in B minor, Brahm's sonata for violin and pianoforte in A major, Brahm's pianoforte solo, and the César Franck sonata for violin and pianoforte. The entertainment is under the patronage of Her Royal Highness the Duchess of Albany.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Local Government Board: Medical Department.

THE estimates of the expenditure on the medical department of the Local Government Board have now been prepared. There is an increase of £324 in salaries, which now amount to £11,923, and an increase of £133 has been provided for in the National Vaccine Establishment, but the total sum asked for is considerably less than a year ago owing to reductions under the head of incidental expenses in the Vaccine Establishment. As was the case last year £1900 are asked for in respect of the auxiliary scientific investigation concerning the causes and processes of disease.

The Disposal of Sewage.

The following statement on the work of the Royal Commission on the Disposal of Sewage has been issued along with the estimate of the expenditure which will be incurred during the ensuing year: "This Commission was appointed in May, 1898, and on July 12th, 1901, they issued an interim report. On July 7th, 1902, they issued a second report, presenting reports on certain chemical and bacteriological investigations in relation to sewage disposal which had been made under the direction of the Commission. On March 2nd, 1903, the Commission presented a third report dealing with trade effluents and the setting up of rivers boards and a central authority for the purpose of settling disputes between manufacturers and local authorities and for the better protection of rivers and other waters. On Dec. 28th, 1903, the Commission presented a fourth report dealing with the dissemination of disease by means of contaminated shell fish and other evils caused by the discharge of unpurified sewage and trade effluents into tidal waters. This report contains the recommendations of the Commission for remedying these evils. The Commission have also presented with this report reports by their own officers on bacteriological examinations of shell fish and sea water, on land treatment of sewage, and on methods of chemical analysis, together with other reports. The systematic investigation of a number of artificial processes of purifying sewage for the purpose of ascertaining their relative value in different circumstances is still in progress. The Commission have not been appointed for any definite period and it is impossible to state with any degree of precision when they will be in a position to make a final report on the questions submitted to them. It may, however, again be pointed out that some of the questions can only be properly determined after careful and prolonged scientific research."

Notes, Short Comments, and Answers to Correspondents.

A LOCUM-TENENT AND HIS PRINCIPAL.

To the Editors of THE LANCET.

SIRS,—Can you advise me how to act in the following circumstances? Being ill, I engaged a locum-tenent (A) with a view to purchase the practice or a share of it. Discovering after a time that A was not in a position to purchase, an assistantship was proposed. A making objection to signing the bond I put a stop to negotiations and gave him his *congé*. He had been with me nine weeks. Since then A has taken rooms in the neighbourhood and has continued to attend certain patients of mine on his own behalf, showing round a testimonial he had received (from a patient of mine) and stating that I was old and past work and inviting them in the circumstances to employ him. He has also given out that he has purchased half my practice and that he is doing all the work. Have I any redress? With apologies for troubling you, I am, Sirs, yours faithfully,

BETA.

*** Our correspondent's only remedy is a legal one. If he can prove his allegations he would certainly also convict the locum-tenent of unprofessional conduct, but we doubt if the General Medical Council would regard the conduct as constituting "infamous conduct in a professional respect." A lawyer might, however, advise Beta that the publication of the testimonial in question was a libel. If Beta could convict Alpha of uttering a libel the unfair rivalry would not only cease but the General Medical Council would have a definite offence before it and might proceed to remove the offender from the Register.—ED. L.

HOLMAN TESTIMONIAL FUND.

Considering Dr. Holman's great public services to the medical profession there should be no difficulty in obtaining the sum necessary to commemorate his labours in a worthy manner.

THE INSTRA WARMER.

THE essential feature of this handy local warming apparatus is the material used in it for the maintenance of slow combustion. The warmer consists of a metal case into which a rod of fuel is placed [illegible] The [illegible] of an [illegible] tilla- [illegible] the interior space provided for the fuel. The apparatus is quite useful and effective when local warmth is desired, as for the hands or feet in cold weather. It may obviously have a number of applications and has been used for medical purposes. A specimen of the patent Instra Warmer was sent to us by Messrs. J. S. Barwick and Co., 6, Strand-on-the-Green, Chiswick, W.

THE FACTORY GIRLS' COUNTRY HOLIDAY FUND.

THE hygienic, educational, and social benefits which this admirably conducted fund confers annually upon some 3000 working girls of London are clearly set *forth in the report of the fund for the year* 1903 which has just been issued. We have several times urged the claims of this fund and pointed out the good which it does for the workers in our great metropolis and the effect which the health of these girls in the natural course of things may have upon the coming generation. The number of women and girls sent away during 1903 was 3600, an increase of 400 as compared with the figures for 1902. The amount contributed by the girls towards their holidays in 1903 was £1013, as compared with £784 in the previous year. "Much as we should like all working people to be able to provide their own holiday," say the committee, "we do not feel justified in keeping hundreds of over-worked, and often sickly, girls waiting for years in London until their wages enabled them to pay the whole instead of part of the cost of the much-needed rest and change." Nevertheless, the fund waits and hopes for a day when its existence will have become unnecessary. In the meantime the most valuable part of its work is the quiet but effectual preparation and education of our working girls for the coming of that happy day. Subscriptions and donations should be sent to the honorary treasurer, Mrs. Bedford, St. Peter's Rectory, Saffron-hill, London, E.C. It may be pointed out that as arrangements for these holidays have to be made some time beforehand subscriptions sent early in the year are greatly valued by the committee.

DR. J. T. C. CONRY'S DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Will you kindly insert the appended list of contributions to the above received since April 5th? Unfortunately, Dr. Conry was not a member of either of the Defence Associations and has consequently had to bear the whole of his costs unaided. The amount received to date represents only a small proportion of what he was called upon to pay. In this connexion may we quote from the kind letter of a contributor of 5*s.*? "As I think that in these cases small subscriptions (which all can afford) should be given by every man in practice to mark his support of a falsely accused brother I therefore enclose an order for the small amount of 5*s.* ...... I would suggest that in the letter which I presume you will send that you will emphasise this point of small but general subscriptions, as many who cannot afford their guineas are often deterred from sending amounts which look so paltry in a list of big subscriptions, but whose mite expresses as much sympathy as the bigger amount."

We are, Sirs, yours faithfully,
EDWIN T. ENSOR.
162, Ladbroke-grove, W., April 12th, 1904. WALTER L. ROBERTS.

A COOLING CUSHION.

WE have received from Messrs. Von Saal and Co., 9 and 10, Australian-avenue, E.C., a specimen of a cooling pad which it is said gives relief in certain kinds of headache and in sleeplessness and fatigue. The cushion consists of a pad containing a spongy material inclosed in a suitable case. On one side of the case is a waterproof sheet while the other side consists of chamois leather studded with several rows of metallic wires. The pad is dipped in cold water before application to the surface of the body, the wires coming into contact with the skin. On application a decided sensation of cold is experienced which in some instances may be useful in relieving certain local conditions. The pad is light and pliable and adaptable to any part of the body, and would seem to possess some of the advantages claimed for it. The metal bars or wires would appear to conduct the heat of the part to which the pad is applied to the moistened sponge where it dissipates. By this arrangement the cooling properties of the pad are assumed to last for some time during a single application.

UNAUTHORISED TESTIMONIAL.

To the Editor of THE LANCET.

SIR,—Last year you called attention to a testimonial purporting to be given by me in favour of "Dr. Whitefoords Pills." I wrote a repudiation of it at the time which possibly never reached you since I have not seen the contradiction of the authority for the "testimonial" in your columns. As I find that it is again being circulated will you allow me to clearly indicate that I have neither given nor authorised in any way such testimonial to anyone.

Truly yours,
1, Elm-court, Temple, E.C. H. S. SCHULTESS YOUNG.

⁂ In our issue of March 21st, 1903, we mentioned that a person named Whitefoord, whose case had been watched by Mr. Schultess Young in a case of procuring abortion (and who had been struck off the rolls of the medical profession for committing that very offence), was circulating a testimonial from Mr. Young to the merits of a quack pill. We received from Mr. Young no repudiation of the honour thrust upon him by his client. Three months later, in our issue of June 27th, we reported Mr. Young as defending Whitefoord on a charge of falsely pretending to be on the Medical Register, so that Mr. Young does not seem to have cherished any resentment against the circulator of the testimonial, although now, a year later, he asks us to publish a letter denying that he ever gave it.—ED. L.

A SERIOUS CHARGE.

A PERSON who was arrested at Southampton last week, and subsequently released upon a small bail, is said to possess medical qualifications but his name does not appear on the Medical Register. He is accused of having impersonated Mr. Charles Henry Cormac, whose address in the Medical Directory for 1903 was "uncommunicated," but who is included in the Medical Directory for 1904 in the list of Practitioners Resident Abroad. The accused, whose real name is given as Hurstwick, claims to hold qualifications gained in Glasgow and Heidelberg, and explains that he has signed a death certificate with Mr. Cormac's qualification derived from the Royal College of Physicians of Ireland through inadvertence. We suppose that we shall hear later if Mr. Cormac's name, as well as his diploma, has been assumed through carelessness and with no intent to deceive.

MEDICAL CERTIFICATES AND SCHOOL AUTHORITIES.

THE medical men of Rugby unanimously refuse to give medical certificates for children in case of their absence from school. On April 12th Mr. Busson was summoned at Rugby police-court for his child being absent from school. Mr. Thomas Johnston, the medical attendant, was subpœnaed on behalf of the defendant and on his evidence the case was dismissed with costs against the school authorities, Mr. Johnston being allowed a fee of 10*s.* 6*d.* We do not know what the relations between the medical men of Rugby and the school authorities of that town have been, but we presume from the fact that the medical men have decided to give no certificates that the school authority has acted in the same foolish way in which for some time the moribund London School Board used to do. We always advised London medical men never to give a certificate for a school board but to tell the parents of the child that they would attend the police-court if necessary. In several cases where this was done the school board failed to get a conviction and the same failure obtains, it would appear, at Rugby.

AN ILL-ADVISED BID FOR PRACTICE.

To the Editors of THE LANCET.

SIRS,—It has been suggested to me to send you the inclosed. It is a discredit that anyone with an English diploma should be permitted to issue such circulars.

I am, Sirs, yours faithfully,
H. WILLINGHAM GELL, M.A., M.B. Oxon., M.R.C.S. Eng.
Hyde Park-square, W., April 6th, 1904.

[INCLOSURE.]

6, Hertford-street, Mayfair, W., March 16th, 1904.

DEAR SIR,—I take the liberty of enclosing you one of my cards, believing that many members of the medical profession would be glad to learn of a dentist who practices *strictly* from "the standpoint of saving the natural teeth."

I may also add that I make a speciality of crowning, bridging and contour work generally, as well as treating all conditions of the mouth and teeth.

I shall be very pleased if at any time I can place my services at your disposal. I am, very sincerely,
To H. W. Gell, M.R.C.S. L. N. SEYMOUR, D.D.S., L.D.S. Eng.

⁂ Mr. L. N. Seymour, who has recently obtained a place on the English Dental Register, and who styles himself "American Dentist" on his card, is very ill-advised to intrude in this manner upon strangers.—ED. L.

THE LEOPARD SKIN.

WE have received a signed artist's proof of Mr. I. Snowman's picture, "The Leopard Skin," which was exhibited in the Royal Academy last year. The picture is the "bonus picture" which has just been issued to their clients by Bovril, Limited. Purchasers of Bovril receive coupons of face value varying with the size of the bottle purchased until coupons to the aggregate face value of a guinea have been accumulated when they can exchange them for a copy of the picture. The picture, it may be remembered, represented the various emotions aroused in a highly decorative group of children upon first being confronted with the new drawing-room hearthrug—a leopard skin, head, claws, and tusks complete. The reproduction has been carefully executed.

◆

Touting for Patients.—The author of the communication bearing this title has not sent his address, his name is not legible, the rules of the medical aid association are not inclosed, and he offers no proof of the distribution to the patients of other medical men of the offending circulars. We can notice the matter if the omissions are rectified.

M.R.C.S.—Among the smaller and less expensive works are "Practical Methods of Urine Analysis" (London: The offices of the *Chemist and Druggist*), Dr. E. Gérard's "Traité des Urines" (Paris: Vigot Frères), and Dr. H. Aubrey Husband's "Examination of the Urine" (E. and S. Livingstone, 15, Teviot-place, Edinburgh).

D. B.—We do not prescribe either medicines or cosmetics for patients. Our correspondent's medical man can advise her as to whether she requires an eye-wash, and might be able to give an opinion as to the advisability of her bleaching her hair.

Anon.—We have no information of the stuff called "the priceless cure," but if our correspondent likes to send us some we will analyse it. The pamphlet shows the proprietor to be the usual quack.

Hope Deferred, who has not sent his name and address, should consult his medical man. The condition, though obstinate, is curable.

R. B. S.—We are unable to verify the quotation and our correspondent has omitted to mention what preparation is being advertised.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

METEOROLOGICAL READINGS.

The Hunterian Lectures
ON
FRACTURES OF THE SKULL.

Delivered before the Royal College of Surgeons of England on Feb. 29th and March 2nd and 4th, 1904,

By LOUIS BATHE RAWLING, M.B. Cantab., F.R.C.S. Eng.,
SENIOR DEMONSTRATOR OF ANATOMY, ST. BARTHOLOMEW'S HOSPITAL.

LECTURE III.[1]

Delivered on March 4th.

Implication of Nerves in Basic Fractures.

Mr. President and Gentlemen,—I have already shown that fractures of the base tend to involve many of the basic foramina. The nerves, however, which make their exit through these foramina are protected by strong dural sheaths, which fact accounts for their frequent escape from injury. Nevertheless, many of the nerves are liable to injury and I propose, therefore, to discuss briefly each nerve in turn with respect to this special liability, indicating the particular fracture present, with the result and prognosis.

1. *The olfactory nerve.*—The great majority of fractures involving the anterior fossa pass through the weak cribriform plate of the ethmoid and necessarily injure the fine filaments of the olfactory bulb. The bulb itself may be lacerated, with or without injury to the neighbouring parts of the under aspect of the frontal lobes. Such an injury may also be produced as the result of a blow over the occipital region, an exemplification of laceration by contre-coup. Sir Prescott Hewett considered that loss of smell is most frequently the result of blows on the back of the head. My experience, however, goes to prove that anosmia, unilateral or bilateral, transient or permanent, results almost invariably from direct fractures involving the cribriform plate. The actual proof of an immediate loss of smell is difficult to arrive at since the nares are usually blocked by blood clot, &c., but a careful examination at all stages of the illness and of the convalescence shows that temporary loss of smell is common, whilst permanent anosmia is rare.

2. *The optic nerves.*—Cases have from time to time been recorded of complete and sudden blindness of one eye following a severe head injury, and at first sight this result is not easily explained, since the great majority of fractures in the vicinity of the optic foramina tend to pass to or from the cribriform plate between the two foramina or more externally through the sphenoidal fissure. Small fissured fractures not infrequently radiate to the optic foramina, but they are usually of so slight a nature as to be incapable of causing any gross lesion of this nerve. No doubt hæmorrhage into the sheath of the optic nerve is responsible for a certain small proportion of these cases but taking into consideration the very common existence of a fracture through the base of the anterior clinoid process, and the frequent dislocation of the fragment, it is highly probable that the loss of vision is secondary to a fracture tearing off the corresponding anterior clinoid process, the fragment compressing or tearing the optic nerve beneath. These cases are so rare that I am only able to put this forward as a suggestion.

3 [illegible] *the* [illegible] *fifth* [illegible] the outer wall of the cavernous sinus is never subject to such injury as to result in anæsthesia of the parts supplied by all three of its terminal divisions. The extravasation of blood into the peri-orbital tissues may, however, result in a complete loss of function of one or more of its branches and cases are recorded where there has been complete anæsthesia of both cornea and conjunctiva with subsequent ulceration and sloughing. The nasal branch may alone be implicated as the result of a fracture involving the cribriform plate and the supra-orbital and supratrochlear divisions may be damaged by a fracture of the vertical plate of the frontal bone. When the anæsthesia is the result of pressure from extravasated blood the prognosis is favourable, but when a nerve is involved in the fracture the anæsthesia is generally permanent. The *third* nerve is similarly liable to injury in its orbital course, the only peculiarity being that some of its branches are picked out and the others left uninjured. The *fourth* nerve is occasionally involved but always in conjunction with other nerves.

The second and third divisions of the fifth nerve.—The foramen rotundum and the foramen ovale lie anterior to the petro-sphenoidal suture, along which suture most middle fossa fractures pass. These two nerves consequently escape direct injury, though they may rarely be involved, together with the first division of the fifth nerve, through implication of the Gasserian ganglion. In 1852 H. Lee[2] reported a case where seven weeks after the injury the following symptoms were present: anæsthesia of the left face and forehead, anæsthesia of the anterior two-thirds of the tongue on the left side, anæsthesia of the left nostril, weak left masticatory muscles, and opaque left cornea. The fracture peculiar to such cases is one in which the terminal part of the apex of the petrous bone is broken off in an antero-posterior direction, the fracture traversing the cavum Meckelii. These fractures are rare and I have only seen two cases.

The sixth nerve may be either compressed, in conjunction with other nerves, by extravasated blood during its passage forwards from the cavernous sinus or it may be the only nerve paralysed, with consequent abductor paralysis of the eyeball. Such cases are not uncommon and this isolated paralysis of the sixth nerve results from the implication of the nerve as it laterally grooves the dorsum ephippii, which process is occasionally torn across in a fracture passing from one middle fossa to the other. The paralysis is generally unilateral, the fracture crossing the dorsum ephippii in an oblique direction.

The seventh and eighth nerves.—There can be no doubt that the seventh nerve is more commonly involved than any other nerve in basic fractures owing mainly to its complicated intrapetrous course. Köhler records 22 cases in 48 cases of fractured base; Bidwell records 15 cases in 106 cases of fractured base; and Battle records 15 cases in 168 cases of fractured base. My own experience leads me to the view that Köhler's statistics are the more accurate, as 24 cases of facial paralysis, partial or complete, were seen in 60 cases of fractured base, 12 in 32 cases that recovered and 12 in 28 fatal cases.

The question of facial nerve implication is so bound up with auditory symptoms that the two subjects must be treated together and classified into two main groups: (1) early and partial paralysis of the facial nerve, accompanied by a variable degree of deafness; and (2) early and complete paralysis of the facial nerve, accompanied by complete deafness. In the first group are included the great majority of middle fossa fractures, such fractures tending to involve the auditory region, and evidenced, amongst other symptoms, by hæmorrhage from the external auditory meatus. A greater or lesser degree of facial paralysis is usually present, not always obvious at first sight, but requiring a careful scrutiny and comparison of the two sets of facial muscles. The fracture passes inwards along the roof of the external auditory meatus towards the junction of the anterior and internal walls of the middle ear, the membrane undergoing a variable degree of destruction with or without dislocation of the ossicles. The fracture then passes inwards to the region of the petro sphenoidal suture in such a manner that the geniculate ganglion of the facial nerve is exposed and laid bare on the anterior aspect of the posterior fragment. The main trunk of the nerve consequently escapes injury except in the region of the genu, where it may be compressed by blood clot sufficing to produce a partial temporary loss of function. In most cases the clot is entirely absorbed and a complete recovery can be expected. The degree of deafness varies according to the extent of damage done to the membrane and ossicles, such being most extensive when the injury results from a direct blow over the auricular region. In many cases, however, the recovery is complete. In the second class of cases the fracture is quite different. Usually the result of a blow on the occipital region, the fracture traverses the thin cerebellar fossa to the outer margin of the jugular foramen. Thence the fracture cuts

---

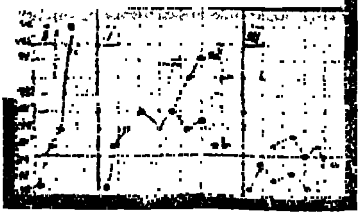
Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

should explain, perhaps, that I am excluding for the present any alteration in temperature due to the onset of septic or pulmonary complications. 5. The rise of temperature is not dependent on any special bony lesion, since the same changes are seen in fractures of the vault and in fractures of the base, anterior, middle, or posterior fossa. 6. *Laceration or contusion of the brain is generally present.* The almost constant presence of some injury to the cerebral substance gave origin to the old theory that the temperature changes are secondary to brain laceration. Against this view, however, several facts can be brought forward: (*a*) Laceration is not always present even when the temperature runs high. In two cases, for instance, the temperature rose to 106° and yet there was no sign of contusion or laceration. (*b*) Laceration, even when extensive, is not necessarily followed by any elevation of temperature. (*c*) The elevation of temperature is absolutely independent of laceration of any particular area. Richet[2] arrives at the conclusion that two hypotheses present themselves, accounting for the elevation of temperature, between which it is difficult to decide. Either there are certain temperature regulators in the encephalon which when excited become stimulated in function, or else the cortical injury acts in a sort of reflex manner on the regulatory centres situated in the pons or in the bulb. Attention is also drawn to the experiments of Lorin and van Benedin who, after excising the two cerebral hemispheres of a pigeon, showed that the heat regulatory power was preserved unaltered, proving that the corpus striatum is probably not the head office of the heat-regulating apparatus. Till, therefore, more evidence comes to hand with regard to heat regulation in general and the effects produced by injury, one cannot go beyond the broad statement that practically all severe cases of head injury show definite thermometric changes, the elevation of temperature not resulting from any special lesion of bone or of cortex but being probably due to the influence of the injury on the heat-regulating centres in the region of the pons or bulb, the temperature progressively rising as the cardiac and respiratory centres fail.

The next point to consider is the value of the temperature chart with regard to the prognosis of the case. All cases of fractured skull can be divided into three main groups, according to the thermometric changes, excluding any alterations secondary to septic, pulmonary, or other complications.

Group 1.—The temperature, at first subnormal, undergoes a steady and progressive rise. The prognosis is most unfavourable.

FIG. 18.



The temperature charts of the three typical groups.

Group 2.—The temperature, at first subnormal, rises gradually to 101° or 102° and then for a short time remains steady. This hesitation marks the crisis of the case, a further rise indicating a probable fatal result, whilst a fall in temperature offers hope of future recovery.

Group 3.—The temperature, at first subnormal, remains at that level, or rises to about normal without any subsequent further elevation. In the former case the patient, owing to the severity of the injury, never recovered from the stage of collapse, whilst in the latter case the injury was of so comparatively slight a nature that the stage of shock, being neither prolonged nor deep, was not subsequently followed by the stage of reaction.

These three groups of thermometric changes are so constant that I regard the temperature chart as the surest and as an almost infallible guide to the prognosis of the case. With regard to any alteration of temperature on the two sides of the body, in spite of an occasional relative increase of temperature on the side opposite to the injury, I have not been able to satisfy myself that such changes are sufficiently constant as to be of any diagnostic value.

CHANGES IN THE FUNDUS OCULI.

In 1887 Edmunds and Lawford published a paper in which attention was first drawn to this subject and statistics were given stating that optic neuritis was present in 12 out of 24 cases of head injury. A subacute basal meningitis was considered to be the cause of this neuritis. In 1890 Battle gave details of 17 cases, in five of which optic neuritis was diagnosed, and he suggested as a cause laceration of the under aspect of the frontal lobes. On reading these statements two questions must arise. Firstly, Are the explanations offered satisfactory; and secondly, Why should optic neuritis develop in cases of head injury uncomplicated by secondary septic infection? These points induced me to examine all cases that came under my notice, an examination of the fundus being carried out at all stages of the illness, with the result that two distinct varieties of fundus change were seen: (1) a disc with normal outline, the fundus, however, showing marked engorgement of the retinal veins, with small arteries; and (2) a fundus presenting all the signs of true optic neuritis. This latter variety was seen only in those cases which subsequently succumbed from septic meningeal infection, whilst the venous retinal engorgement was of common occurrence.

Now, one of the most striking features in the post-mortem examination of cases of head injury is the great engorgement of the superficial cerebral veins and this venous congestion is seen equally in fractures of the vault and in fractures of the base, with or without brain laceration, and also in cases of mere concussion only. The retinal engorgement is early in onset, being frequently seen within a few hours of the injury and long before any true optic neuritis could develop. It is most marked when the injury involves the anterior segment of the skull and it is not necessarily accompanied by laceration of the under surface of the frontal lobes. It is, however, most common when a fracture traverses the sphenoidal fissure or involves the cavernous sinus. As the patient improves, so also does the congestion diminish in direct ratio, any later development of true optic neuritis indicating the onset of an acute or of a subacute meningitis. I regard, therefore, this retinal venous engorgement as part and parcel of the general cerebral venous stasis, the condition being of no great clinical value with regard to the presence or absence of any fracture. Dr. Fleming has recently pointed out that retinal hæmorrhages are almost invariably present in basic fractures and, further, that when the subarachnoid hæmorrhage and venous congestion are unilateral the retinal hæmorrhages are mostly confined to the affected side. The subject of "optic atrophy" has been briefly discussed under "implication of nerves."

BRAIN LACERATION; CONCUSSION AND COMPRESSION.

Of all complications of fracture of the skull injury to the brain substance must be regarded as of the greatest importance, for on the presence or absence of such a lesion the ultimate result in the majority of cases depends. Some contusion or laceration of the brain is almost invariably present when the injury results from a fall from a height, the lesion varying from a mere bruising of the cerebral cortex, with extravasation of blood and serum into the subarachnoid space and into the meshes of the pia mater, to complete laceration of certain of the cortical areas. No part of the brain can be said to be exempt from such injuries, for though it *is far more common to find* laceration of the frontal and temporo-sphenoidal poles, yet one not infrequently finds laceration of the Rolandic area, of the occipital poles and cerebellum, and even of the deep nuclei of the brain. The relative frequency with which these various areas are injured is: (1) the anterior and inferior aspect of the frontal poles; (2) the anterior aspect of the temporo-sphenoidal poles; (3) the Rolandic area; (4) the occipital poles; (5) the cerebellum; and (6) the deep nuclei and the deep cortex.

Laceration may be seen directly beneath the seat of primary osseous injury or on the surface of the brain over an area exactly opposite to that at which the injury was received. Various theories have been brought [illegible] to across the petrous bone, external to the internal auditory meatus, and terminates usually by comminuting the tegmen tympani. It is in this transpetrous course of the fracture that the irreparable damage is done, for not only is the facial nerve cut clean across in the region of the genu but the auditory apparatus is also severed into two parts. The exact line of the fracture is shown in Fig. 15. The outer fragment is the more interesting and the next two figures explain in detail the parts involved. Fig. 16 shows the open mouths of the semicircular canals, the outer parts of the fenestra ovalis, of the promontory and of the fenestra rotunda, and the exposed mastoid antrum, whilst the malleus, the incus, and the membrane are absolutely uninjured. In Fig. 17 the comminution of the tegmen is more extensive but otherwise the parts exposed are similar to the preceding

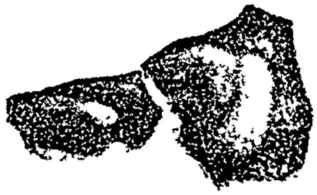
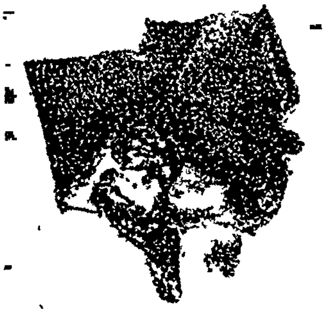
FIG. 15.



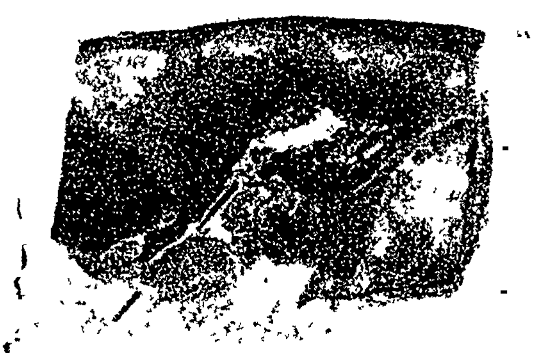
Right petrous bone, showing a fracture running in the antero-posterior direction. The internal auditory meatus is seen.

FIG. 16.



The outer fragment of the same specimen viewed from the inner side showing the semicircular canals, the facial aqueduct, the ossicles, and the membrana tympani.

FIG. 17.



A more extended fracture of the right petrous bone. This specimen also shows the inner aspect of the outer fragment together with the mastoid antrum, a probe in the facial aqueduct, the ossicles, the membrana tympani, the semi- rcular canals, the internal carotid artery, a probe in the tachian canal, and the foramen ovale.

ddition, however, the specimen shows that the
lves the petro-sphenoidal suture, passing
foramina ovale and spinosum but anterior to
the horizontal part of the internal carotid artery. The long probe is passed along the Eustachian tube and the smaller is insinuated into the horizontal part of the aqueductus Fallopii. In these cases, therefore, though the facial paralysis and deafness are both complete and permanent, there is no external auditory hæmorrhage.

Two points further need reference, the first being the rare variety of fracture described by Léon Boullett in 1878, under the title of "fracture of the mastoid portion of the temporal bone" secondary to direct blows on the mastoid process, with a consequent separation of that process from the rest of the skull, the facial nerve in the descending part of the aqueduct usually being injured. Lastly, *late* paralysis of the nerve is occasionally seen after the lapse of a few days, secondary either to a septic infection with an ascending neuritis or to the organisation of the blood clot around the genu of the nerve. The diagnosis between these two conditions is simplified by the presence or absence of pyrexia, rigors, vomiting, &c.

The ninth, tenth, and eleventh nerves.—The jugular foramen lies in the path of more than one line of basic fracture. The nerves, however, are well protected and usually escape injury. Cases are now and again seen in which the result is less favourable, the following being a brief abstract of such a case. The patient was admitted with a fracture of the posterior part of the parietal bone and for four days, beyond restlessness, no special symptoms were evident. On the fifth day there was a sudden attack of severe dyspnœa with diaphragmatic respiration only. The conditions improved till the sixth day, when he was again seized with another attack of acute dyspnœa, accompanie by dysphagia, during which death occurred. The exa

or dilatation on this side (Surminski, Langendorff), or (3) that on the side with the ganglion the dilator is inhibited (Kowalewski).

After the local application of eserine to the eyes of a kitten the pupil is smaller on the side from which the superior cervical ganglion has been removed so long as the kitten is quiet, but slight dyspnœa will cause the pupil to become almost maximal, though the normal control pupil is very [illegible] when the sphincters [illegible] instead of under the [illegible] pupillo-dilatation must, therefore, result from an actual increase of tone in the dilator on the side without the ganglion. This increase of tone may be directly demonstrated in the nictitating membrane and lids. The paradoxical effect is therefore due to an increased excitability of the contractile tissues on the side without the ganglion (Lewandowski, Anderson). The great accentuation of the paradoxical effect seen under anæsthesia does not occur until dyspnœa arises. If only the [illegible] paradoxical effects occur much [illegible] unced. The paradoxical effects [illegible] not inhibit the automatic ex[illegible] tissues with which it is still [illegible] cannot inhibit the paradoxical [illegible] nerve, since the effect will still persist in bright sunlight for more than a minute.

Inhibition of antagonists.—It is known that in the case of the ske[illegible] panied [illegible] group ([illegible] probable that constriction of the pupil through the third nerve should be accompanied by simultaneous active inhibition of the dilator, also carried out through the third nerve by means of inhibitory dilator fibres. And, indeed, [illegible] consideration of the electrical [illegible] contraction of the sphincter, [illegible] happened. Anderson (1903), however, has [illegible] view. Thus, [illegible] of the sphinc[illegible] may arise a[illegible] hibition of the sphincter [illegible]

The iris is not under [illegible] the motor nerves are invariab[illegible] by reflex stimuli or by wh[illegible] i.e., association with other voluntary or involuntary movements.[2] There are two chief reflexes and two chief synkineses or associated movements: (1) the light reflex; (2) the accommodation synkinesis; (3) the sensory reflex; and (4) the cerebral synkinesis.

The light reflex.—This is carried out entirely through the mechanism of the constrictor centre. Of the afferent paths we know very little for certain. The fibres are contained in the optic nerve and they arise from all parts of the retina. The optic nerve contains large and small fibres; it is possible that the large fibres are concerned with visual sensations and that some of the fine ones are afferent pupillo-constrictor fibres. The opposite view has also been advanced. It is certain that the pupillary fibres undergo partial decussation in the chiasma and enter the optic tracts. It is also certain that they do not enter the lateral geniculate body but leave the tract to pass by a path which is as yet conjectural to the third nucleus. The tone of the constrictor centre is kept up by constant afferent impulses along this tract; it is possible that it also possesses inherent tone The tone is probably continually depressed by less effectual impulses along the fifth and other sensory nerves.

The accommodation synkinesis—This is a constrictor effect commonly associated with accommodation. It is more nearly related, however, to the convergence which normally synchronises with accommodation, since it is possible to accommodate without inducing constriction of the pupil, whereas this invariably occurs during convergence. Very little is known about this phenomenon; even the views stated are open to doubt, but there can be no doubt that it is not a true reflex but a case of associated movement. The same remark applies to the well-known lid-closing phenomenon.

The sensory reflex.—This is a dilator reflex induced by tactile, pathic, and other sensory stimuli. It is a complex effect exhibiting a primary rapid dilatation due to augmentation of the dilator tone through the cervical sympathetic followed by a second dilatation rapid in onset but very slow in its disappearance due to inhibition of the constrictor tone. When originated through spinal sensory nerves the afferent impulses are carried up in the posterior columns of the cord.

The cerebral synkinesis is also a complex phenomenon and cannot be considered a true reflex. It is induced by psychic stimuli—e.g., fear, &c.—and also by concentration of thought upon a bright light or a dark room. It is also largely an associated movement, accompanying eye movements which may be themselves due to sensory impulses. The pure psychic reaction, entirely caused by ideas of light and shade, was described by Haab (1886), though Beer had long before discovered that he was himself able to alter the size of his pupils in this manner; it may account for some cases in which persons have apparently been able to alter their pupils at will. The phenomenon is unaccompanied by any obvious movement of the eyes and therefore cannot be called a synkinesis; it is, in fact, a *psychokinesis*. The reaction has recently been called in question by Bumke (1903) and it must be admitted that it is very difficult to exclude the many sources of error, of which accommodation is the most probable and difficult to avoid.

I propose now to discuss in detail my observations on the relationship of the cerebral cortex to the movements of the pupil, devoting such time as remains to the results of other recent researches.

Fontana, as long ago as 1770, showed that in the cat, even under the strongest light stimulus, the pupils dilated widely if the animal was frightened by a loud noise. A child's pupil can also be made to dilate, even during ophthalmoscopic examination of the macula, by a loud sound, such as clapping of the hands. Raehlmann and Witkowski consider that psychic impulses assist in maintaining the tone of the dilator centre, accounting for the constriction of the pupil during sleep by their absence. Schiff and Foa (1869) first stimulated the cerebrum by electricity and obtained dilatation of the pupils from stimulation of the anterior four-fifths, and of the cerebellum only by strong stimuli. They attributed the effect to the sensibility of the brain. Hitzig (1871) sometimes obtained constriction of both pupils, but generally dilatation; rarely only one pupil reacted. Similar experiments have been carried out by Bochfontaine (1875), Danilewski (1876), Luciani and Tamburini, Grunhagen, Bessau, Ferrier, Horsley and Schäfer, Schäfer, Beevor and Horsley, Grunhagen and Cohn, Katschanowski, François-Franck and Pitres, Mislawski, Bechterew and Mislawski, and Braunstein. In most of these cases the observations were incidental during research directed to some other object In all dilatation was much more easily induced than constriction and no accurate localisation was effected [illegible]

Most observers have regarded [illegible] but little attention has been [illegible] Thus Ferrier includes dilatation [illegible] from the submaxillary gland, [illegible] pressure, and "other indications of general reverberation throughout the organism." He regards them as "merely complications and not as results of localised cortical stimulation". On the other hand, Bechterew and Mislawski conclude that "stimulation of the given regions of the cortex and of the optic thalami has hit off the central endings (Verlungerungen) of the cervical sympathetic" and that "the chief reflex centre for the secretion of tears lies in the optic thalami, and that there too are found the central tracts of the cervical sympathetic, their prolongations (Fortsetzungen) being continued thence to the cortex." [illegible] causes François-Franck [illegible] lation. [illegible] of dilatation of [illegible] ion of One is a special [illegible] definite foci in the cortex and also obtained from excitation of the underlying fibres of the corona radiata and internal capsule. The other accompanies epileptoid convulsions [illegible] every part of the [illegible] —bite [illegible] the [illegible] of [illegible] by [illegible] ntaine. He perhaps [illegible] lumental distinction, [illegible] ts induced through [illegible]

---

[2] The corresponding term for the association of [illegible] associated ideas, would obviously be "synpsychosis."

I have not paid much attention to any movements other than those of the eyes and pupils. Dilatation of the pupils is often obtained without any movement of the eyes or body. I have usually found that a slightly stronger stimulus is necessary to evoke it than that which is required to produce movement from excitation of the arm or leg areas, or the same strength of stimulus may suffice if the animal be slightly less under the influence of the anæsthetic.

(*a*) *Cat.*—In the cat dilatation of the pupil can be obtained from a considerable area in the neighbourhood of the crucial sulcus and from a considerable area of the occipital region. As the result of many experiments it is found that the mesial surface of the hemisphere near the crucial sulcus (prorean and presplenial convolutions) gives the most marked effect, but I have also found that the anterior part of the third or median convolution (coronal or anterior supra-Sylvian) gives a very constant effect. In one or two instances there was a transitory constriction of the pupils before the dilatation from this area. Ferrier obtained constriction of the pupils and divergence of the eyeballs from this spot in the dog but I have not observed the latter effect in the cat.

My experiments were made principally upon cats; a few dogs and one monkey were also used. The animals were anæsthetised with ether, the degree of anæsthesia varying, but always being amply sufficient to cause insensitiveness to pain. The qualifying terms used apply to the condition of excitability of the motor areas of the cortex to stimuli of moderate severity, as shown by movements of the limbs of the contra-lateral side. "Epileptoid convulsions" is the term used to express the violent general movements which often follow stimulation of the motor area after exposure of the brain to air or prolonged or frequently repeated excitation. This condition is quite compatible with complete anæsthesia. The cervical sympathetics were either cut or isolated on one or both sides. In the dog the vago-sympathetic was treated as a whole. This was also done sometimes in the cat to insure the complete division of all sympathetic fibres. In some experiments the superior cervical ganglion was extirpated to eliminate any dilator fibres which might reach the ganglion by any hitherto unknown course Section of the sympathetic was usually followed by a distinct moderate constriction of the corresponding pupil but this was certainly not invariably the case. Absence of a tonic dilator influence is probably in these circumstances due to the condition of anæsthesia of the animal. I need not enter into further details of the operative procedures, which were those usually employed in cerebral physiology. It was important to keep the light falling upon the eyes as constant as possible throughout the experiment. It is easy in the cat's eyes to direct one's attention to the horizontal meridian. The constricted pupil being a vertical slit, the distance from the centre to the periphery can be divided into four imaginary parts, the pupil being said to be a quarter, a half, three quarters, or fully dilated.

In the occipital region what may be called the focal spot is in the posterior part of the third or median convolution (posterior supra-Sylvian convolution). I have not observed any constriction of the pupil here, as described by Ferrier. François-Franck, however, obtained a transitory constriction from this spot, followed by dilatation, exactly like that which I describe for the coronal gyrus. It is therefore probable that there are foci for pupil-constriction both in the frontal and occipital areas but that they are masked by the dilator effects which are much more readily produced. One may compare with this the greater representation of lateral eye movements over any other eye movements in the cortex.

Only the results which are deduced from a large number of carefully planned experiments can be considered trustworthy, more particularly in deciding between areas which give a positive result independently of epileptoid convulsions. These are very readily brought about by repeated excitation of the same or closely neighbouring areas owing to the increased excitability of the cortex which is thereby induced. The condition of anæsthesia is also of the utmost importance. If this is deep the pupils remain immobile. If it is too light dilatation is obtained from almost every part of the cortex, at any rate when bodily movements occur. The resul[illegible] only reliable when the anæsthesia is moderate [illegible] The areas are very much the same in the dog a[illegible] This animal is less suited for the purpose b[illegible] rarity of dogs with light-coloured irides, and a round pupil is less easy to detect slight variations upon than the slit-like one of the cat. In the dog I obtained a very marked effect from the precrucial gyrus, but I failed to observe any convergence of the optic axes as noted by Ferrier.

(*c*) *Monkey.*—I have done only one experiment of this nature upon the monkey. I found it much the easiest animal to work with and it gave very definite results.

I conclude from these experiments that previous section of the cervical sympathetic diminishes the effect but by no means abolishes it. When both cervical sympathetics are intact the dilatation of the pupil when well marked is accompanied by all the usual effects of excitation of the nerves themselves—viz, retraction of the nictitating membrane, widening of the palpebral aperture, and projection of the eyeball; to these Bechterew and Mislawski add secretion of the lacrymal gland, but this I am unable definitely to confirm. All these effects are abolished by previous section of the sympathetics except the dilatation of the pupils, and this is diminished. Whereas when the nerves are intact full dilatation of the pupils may occur, especially during epileptoid convulsions, after they are divided the pupils rarely become more than three-quarters dilated. The effect is very well seen if one nerve is divided, the other being intact. In this case the two pupils move synchronously and apparently to the same extent, except that they start unequal, the one on the divided side being the smaller. François-Franck is therefore certainly wrong in asserting that the pupillary dilatation is unilateral if one sympathetic has been cut. He certainly admits a slight degree of dilatation, which he attributes to dilator fibres running another course, probably in the trigeminal. I have eliminated this possibility by dividing the fifth nerve intracranially and still obtaining the undiminished effect. To eliminate the possibility of other dilator fibres reaching the superior cervical ganglion I have as already stated, extirpated it. The pupil on the side from which the ganglion was removed was slightly but appreciably smaller than on the side on which the vago-sympathetic was cut.

I have found that section of the third nerve intracranially after previous division of the cervical sympathetic causes the pupil to become immobile, about three-quarters dilated Stimulation of the cortex has then no effect upon it. Complete section of the corpus callosum has no effect upon the result of exciting the cortex. The bilateral effect is therefore not due to the stimulus acting through the opposite cortical areas but to its acting upon lower centres, but whether the optic thalami, or the superior colliculi, or the subcollicular nuclei I am not prepared to say, but probably upon the last mentioned. Stimulation of the anterior and posterior parts of the corona radiata and internal capsule containing the fibres derived from the cells of the frontal and occipital area leads to bilateral dilatation of the pupils. I have generally found a stronger excitation necessary, but this may be due to the fact that stimulation took place at the end of prolonged experiments. In one case I obtained a very marked constriction of the pupils with strong convergence of the eyeballs from stimulation of the posterior part of the internal capsule.

A point of great interest arising from these experiments is the question of the mechanism whereby dilatation of the pupils can occur in the absence of the usual dilator tract. Two explanations offer themselves—viz., inhibition of the tonic action of the third nuclei and dilatation brought about by vascular changes in the iris. An extremely interesting observation by Sherrington may be mentioned in this connexion. In bringing physiological experiment to bear upon current theories of the emotions, he performed "appropriate spinal and vagal transection" in the dog to eliminate "the sensation of all the viscera three-quarter muscles below the shoulder." He says: "The eyes were well opened, and the pupil distinctly dilated in the paroxysm of anger. Since the brain had been by transection shut out from discharging impulses via the cervical sympathetic the dilatation of the pupil must have occurred by inhibition of the action of the oculo-motor centre." It is said that after the optic nerves have been cut dilatation of the pupil is not obtained upon section of the third nerve, and hence tonic action of the third nuclei has sometimes been denied. There can be no question, however, that it exists when the optic nerves are intact, as in my experiments. The immobility which follows section of both the third and the sympathetic is strong evidence in favour of the inhibition theory. It must be noted, however, that the blood pressure was probably very low at this stage of the experiment.

We have seen that dilatation of the pupil is still obtained after section of the sympathetic. No vaso-motor fibres are known to run to the iris except by way of the sympathetic, and even if such exist the experiments of Langley and Anderson tend to show that vascular effects are inefficient to bring about the dilatation observed. Moreover, it is well known that changes in blood pressure may occur from stimulation of various parts of the cortex, whereas pupil dilatation only occurs from certain localised spots in the absence of the epileptoid state. It seems justifiable from these considerations to regard the effect as another example of direct inhibition of the oculo-motor nerves from the cortex.

There is no lack of evidence as to the presence of fibres connecting the cortex with the mesencephalon and some of these must be regarded as the ones concerned in the pupillary effects. We may leave out of the question the dilatation of the pupil which accompanies the epileptoid state, for this is undoubtedly of an extremely complex nature, requiring special investigation. Confining our attention to the more specialised results obtained from the oculo-motor area in the posterior part of the frontal convolutions which are to be looked upon as part of the fronto-parietal motor or kinæsthetic area and quite distinct from the more anterior or so called prefrontal area, and to the results obtained from the oculo-sensory or visual area in the occipital convolutions we find definite anatomical connexions with the lower centres.

The pallio-tectal or cortico-mesencephalic system of fibres has recently been thoroughly investigated by Dr. C. E. Beevor and Sir Victor Horsley. *It is noteworthy that no fibres* were found passing to the mesencephalon from the frontal region—i.e., from the area of cortex in front of the excitable cortex. From lesions of this part there was marked degeneration of the fronto-thalamic fibres previously described by Déjerine; the only mesencephalic centre to which fibres could be traced was the upper or anterior part of the locus niger. No fibres, therefore, go to the tectum. A large number of fibres could be traced from the excitable cortex to the corpora quadrigemina and mesencephalon, especially to the superior colliculus. This was very marked in the cat, much less so in the monkey. The fibres *from the oculo-*motor areas have not yet been specially investigated.

The results from lesions of the occipital lobes were particularly striking and confirmed Edinger's researches on birds. In proportion as more of the area of the cortex containing Gennari's streak is involved in the lesion the number of degenerated fibres passing to the colliculus increases. The fibres are large and stand out distinctly from the medium-sized occipito thalamic and occipito-geniculate fibres and from the small callosal fibres and fine collaterals which enter the corona radiata in large numbers. Some of the occipito-tectal fibres pass among the fibres of Gratiolet's radiation, others run through the mesial region of the inferior longitudinal bundle. All the fibres are distributed to the whole breadth of the stratum griseum profundum of the superior colliculus. Which of these fibres are concerned in the pupillary phenomena, and whether they pass, any of them, directly to the superior pupillo-dilator centre or to the pupillo-constrictor centre, or only by intermediate connexions, must be left for future research to determine. I have already shown that the cortical pupillo dilatation is a complex event, strikingly resembling the ordinary sensory dilator reflex in that it is accompanied by all the usual *effects of stimulation of the cervical sympathetic as long* as that path is intact, but that it also occurs, deprived of the other sympathetic effects, when this nerve is divided. The evidence is therefore in favour of a more circuitous course, or at any rate of multiple and complicated interconnexions.

There is evidence that pupillo constriction can also be elicited from stimulation of the cortex. Ferrier obtained it from stimulation of the anterior and posterior limbs of the angular gyrus in the monkey, but this observation is probably incorrect. I have already stated that I failed to confirm the same observer's result from the third external or coronal convolution in dogs. In pigeons Ferrier found intense constriction of the
middle of the convexity
obtained marked constriction
of the quadrate lobule in monkeys. This brings us to the consideration of the exact nature of the phenomena. The view of Bechterew and Mislawski, that we have here the central prolongations of the cervical sympathetic is, *a priori*, highly improbable, or, at any rate, a misleading explanation of the results; indeed, the continuance of the dilatation after section of the cervical sympathetic proves that it can only be partially true. So, too, it is unlikely that we are dealing with "centres" for the pupils in the ordinary sense of the term We have found that the effect is most specifically obtained from the areas which are most concerned with ocular movements whether from the motor or the sensory side; moreover, it would seem that the effect is indissolubly connected with those movements and does not occur in their absence, hence it is most reasonable to conclude that the phenomenon is an associated effect. As regards the so-called sensory areas—i.e., the visual centres in the occipital cortex—it is probable that the attention plays some part. We produce, by artificial excitation, some strong but probably ill-defined visual sensation which arouses the attention and leads to the appropriate movement of the head and eyes towards the direction from which the stimulus seems to proceed. The sensation is strong and sudden and is accompanied by dilatation of the pupils in no physiological sense other than the expression of emotion.

THE EPIDEMIOLOGY OF ENTERIC FEVER AND CHOLERA IN HAMBURG.[1]

By DR. REINCKE,

MEDICAL OFFICER OF HEALTH OF THE CITY OF HAMBURG AND CORRESPONDING MEMBER OF THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

IN order to understand aright the epidemiology of enteric fever and cholera in Hamburg it is necessary to have a clear picture in one's mind not only of the topography of the town but also of the topographical arrangement of the surrounding district, for the reason that the particular conditions of our locality are in a special manner favourable to the diffusion of enteric fever and cholera from the town to the country and from the country to the town. Hamburg, as you are aware, is situated in the great North German lowland, which is of diluvial origin, made up of glacial drift, sand, clay, gravel, and erratic boulders, scattered pell mell, overlying the tertiary formation, and in many places rising like a plateau to a height of 50 metres and more above the level of the sea. This formation, which is, comparatively speaking, poor in water, is termed by us the "geest." At the sea coast and mouths of rivers lies the alluvial formation, "the marsh," which extends in front of and beyond the "geest." It is, however, only met with in those parts where there are an ebb and flow—that is to say, only at the North Sea, not at the Baltic. These marshes consist of the sediment deposited by large rivers which empty themselves sluggishly into the sea by wide mouths. It is only through the activity of man in building "dikes" or embankments that they are made habitable and secure against floods. In some places they form islands between numerous water-courses; in others they form a wide boundary to the "geest," covering miles of flat expanse at sea bays and mouths of the river. Hence it is clear that the part of the estuary of the Elbe, as far as above Hamburg, once formed a deeply indented bay (Fig 1 gives a picture of these conditions). The marshes are very damp and are intersected by numerous drains which at low tide empty themselves into the river by means of sluices. A somewhat larger drain which flows parallel with the embankment goes by the name of the "Wetterung." The dwelling-houses lie on the inside of the embankment, between it and the "Wetterung," at irregular intervals, in even rows, extending for miles. The fertile land lying behind is used for feeding cattle and growing vegetables.

As naturally follows from such an arrangement of the houses, every kind of refuse from the dwellings, cattle-stables, and dunghills very easily finds its way into the "Wetterung," which at the same time is used for drinking and domestic purposes. For all water from the marsh wells contains so much iron that it cannot be used for drinking purposes. And in cases where the "Wetterung" is not used water is taken from the river outside the embankment, which also cannot be regarded as free from pollution. Those houses are best off that collect rain water from the roof in underground cisterns. You can understand that, in such circumstances, grave insanitary conditions easily arise, although the people in many of the marsh districts are often of almost "Dutch cleanliness." When enteric fever occurs in these districts it can only be stamped out by slow degrees and with much difficulty. In former times it never died out altogether. When the people of Schleswig-Holstein spoke of marsh fever they usually meant enteric fever and not malaria. Such infected marsh villages are at the present day also the source whence the disease is being continually re-imported into the town, especially when these villages are close to a big town, such as Hamburg, with which they keep up regular intercourse in pursuing their market trade, bringing all kinds of goods to the town, more particularly articles of food which have come in contact with infected water in the "Wetterung" and are consumed in a raw state. Mention must first of all be made of milk, which is conveyed in vessels which have been previously cleansed and washed in marsh ditch water; further, different kinds of vegetables, salads, radishes, and fruit, which are probably stored in the drains (or ditches) to keep them fresh till market day.

---

[1] A paper read before the Epidemiological Society on March 18th, 1904.

In bringing forward these circumstances it is, of course, not implied that the "geest" is altogether free from enteric fever. There, too, the disease may be imported, the wells infected, and from them in its turn the milk also. Still, such cases are much rarer there and when they occur are more localised and therefore easier to suppress. Moreover, in the course of time decided improvements have been made in the marsh, particularly by the improvement of the water-supply. This has been effected partly by teaching and introducing methods to free the water of the different wells from its iron, thereby making it usable, and partly by the establishment of central water-supplies from deep-bore wells giving very good water. In addition to this various precautionary measures in connexion with the position of privies, dung-heaps, and slaughter-houses, with the handling of milk and other articles of food, have contributed to the improvement of the sanitary conditions of the district. Still, there can be no doubt that the marsh villages, in spite of all precautions, are continually running risks and are at the same time a constant source of danger to the town.

I believe that in this country also you have small districts at the mouths of the Humber, Trent, Ouse, &c., where the conditions are similar. Dr. R. J. Reece, in a report of August, 1903, to the Local Government Board, described the sanitary conditions in Thorne rural district exactly as we know them to be with us in our marshes. This state of things on the continent is not confined to the neighbourhood of Hamburg but exists also along the whole of the North Sea coast from Schleswig as far as Holland and Belgium. And with slight alterations the conditions in the towns situated in the marsh are the same as those in the country districts. Hamburg was founded by Charles the Great as an advanced seat for a bishopric among the heathen and was built on an elevation in the "geest," or high land, between marshy plains which were not banked in. But soon as temporal interests became more and more important (together with the spiritual interests) the buildings extended into the marshes. And the more the population turned its attention to commerce and shipping the more did the town extend in the direction of the stream into the marshes. Thus at the present day a considerable portion of the town lies in the marsh where houses may only be built after numerous props have been driven deep into the ground for support. These marsh portions of the town have developed from banked-in marsh islands called "Polder," and they are still intersected by numerous water-courses which in Hamburg go by the name of "fleete." They represent exactly the same thing as the "grachten" in Dutch towns or the canals in Venice, with the only difference that in the latter town there is no flowing fresh water but only the salt water of the Adriatic. These Hamburg navigable canals in former times received all refuse from the houses abutting on them and at the same time served as sources of water-supply. We have still old pictures showing this state of things. It is therefore pretty certain that the sanitary conditions in the town were formerly very unfavourable, although definite details are wanting. The danger was not suspected and the value of cleanliness was not recognised till the year 1831, when cholera came and opened our eyes, as well as those of the whole world, to the danger. It was then that your country took the lead, showing a good example, and teaching how towns might be kept sanitary by means of good drainage and good water-supply, and Hamburg was the first continental town to profit by your English experiences. In 1842 our town was visited with a devastating fire, lasting three days, laying in ruins a very considerable portion of it. It was then we turned to your countryman Lindley (who died only lately at a good old age) and he provided not only the newly-built parts of the town but also the remaining old parts of it spared by the fire with a general system of sewerage and a central water-supply, both of which were completed towards the end of the "forties." This was the beginning of improvement in the health of the city and I will show you later, from the curves of enteric fever and cholera, how favourably both measures have acted, in that they not only improved the drinking water but also led to a greater cleanliness in every respect—in house and yard, in kitchen and cellar, in clothing and care of person. We can thus account for the steady decline of tuberculosis in Hamburg since the great fire, to which fact Dr. H. T. Bulstrode recently drew public attention. Unfortunately, this steady progress in sanitation has not continued, because, as is well known to you—and as I am just going to show you in detail—the central water-supply had serious shortcomings.

Before entering on this important part of the subject I should like to speak shortly of the shipping conditions which greatly resemble the conditions in the country districts described above. In so doing I will except the sea-going vessels which, as a rule, have good drinking water on board and the passengers and crew of which do not easily come in contact with the river water. But it is quite another thing with the river craft which come into Hamburg in great numbers from the wide river path of the Elbe and from the Oder and Vistula which are connected with the Elbe by means of canals. There are often as many as 800 and more of such large river craft in the harbour, each of which is manned by a family—a skipper with his wife and children and one or more hands. In spite of all precautionary measures and regulations on the part of the authorities those on board allow their dejections to go into the river from which they at the same time draw their drinking water. Although the habits and mode of living of these people are gradually improving yet they still leave much to be desired and you will understand of what importance it is to a town for the epidemiology of enteric fever and cholera when a very great number of such ships lie close together in its harbours. Naturally, similar dangers arise from the still more numerous small tugs, lighters, barges and boats, and from the numerous businesses and occupations carried on at the water's edge. Nevertheless, these take a secondary place in comparison with the dangers which arise from the river craft, because in all those other cases only men are occupied and that, too, only during the daytime, whereas here women and children are also concerned who have less discernment and who live day and night on the water and can easily, unperceived, take advantage of early morning and late evening to pollute the river.

After this digression I return to the subject of the water service. The water for the central service was from the very beginning taken from above the town, where it was stored but not filtered. This was a marked improvement on the previous state of affairs, as at low tide the fresh water from the upper part of the river was taken in, and as even in high tide the river at this spot was not nearly so polluted as near the town and in the water-courses of the town, where it receives the unpurified sewage of the whole city. Nevertheless, the innate danger consisted in this: that in the case of a low level of water in times of drought, or in the case of spring tides raised higher by the winds, the tidal wave, which carries with it all refuse out of the harbours and sewers, can come much higher up stream than is usually the case. Consequently, part of the polluted material from the town, although in a modified or rarefied form, might reach the intake and enter the pipes. This danger became gradually greater and greater, although the intake was taken higher up the stream. The town at the time of the fire of 1842 numbered about 160,000 inhabitants; in 1884 about 440,000; and in 1903, 740,000. In consequence, as time went on, more and more sewage was emptied into the Elbe; the town buildings and harbours extended farther up the stream, the shipping increased year by year, and regulation works were built, the object of which was to deepen the water-way and to bring more water into the harbour for

FIG. 1

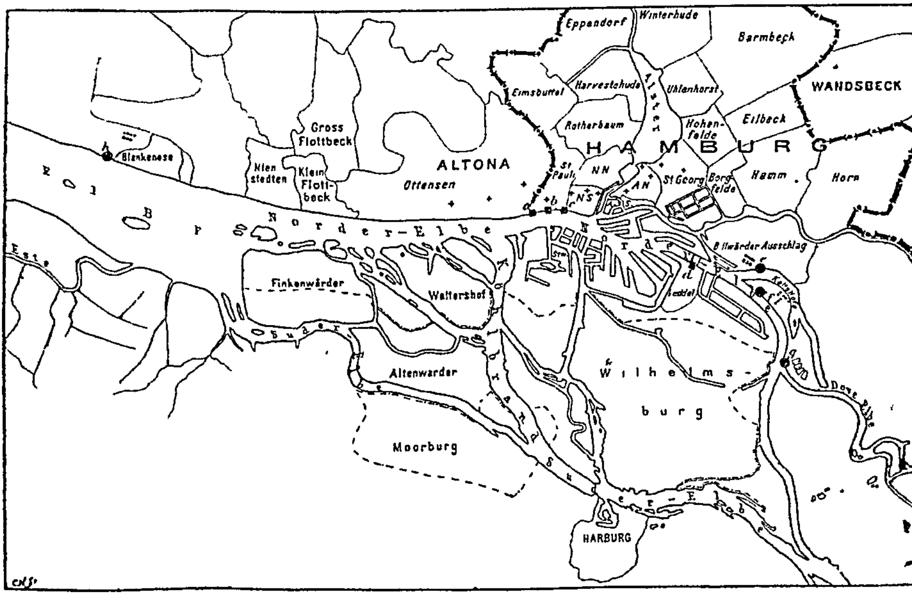
FIG. 2.



Political boundaries of Hamburg. These coincide with the "water area."

ships with a deeper draught. All these circumstances contributed to allow sewage more easily and more frequently to make its way to the intake. Not till the introduction of the central sand filtration in 1893 were all these dangers at an end. I will not take up your valuable time with the details of the development of this state of things which passed through many stages and involved many battles, nor will I trouble you with the proposals to remove the intake still higher up stream. It might not even interest you. For the present purpose you have enough with what I have told you and with that which you can deduce for yourselves from the plan (Fig. 2). I should only like to add that the area of the piping of the water service coincides with the political area of the town. The political boundaries coincide exactly with the boundaries of the water service. On the east, the Prussian town of Wandsbeck, which at the present time has about 30,000 inhabitants, joins on to Hamburg without any visible line of demarcation. This town of Wandsbeck has waterworks of its own supplied from inland lakes in Holstein. On the west of Hamburg lies the Prussian town of Altona, with at the present time about 168,000 inhabitants, which, like Hamburg, gets its water from the Elbe. The waterworks which were built by your fellow countryman, Thomas Hawksley, during the years 1857–59, lie ten kilometres below the town and take therefore the river water polluted by the sewage from both large towns—Hamburg and Altona. Since the opening of the works in 1859 the water has been carefully filtered. Pipes from these works supply the town of Altona almost as far as the political boundaries of Hamburg. In Fig. 2 these boundary lines are shown very distinctly. It is interesting to observe how first one and then the other of the two water services were infected with enteric fever. In the case of the Hamburg service it might happen at any moment; in the case of the Altona service only when the filters were found wanting or when unfiltered water was pumped into the mains. Each of these mishaps occurred often during the first few years of working because the technical detail of filtering had first of all to be learnt and then put into practice, and also because, acting without knowledge of the hygienic dangers of unfiltered water from the Elbe, no care was taken to avoid supplying unfiltered water when repairs were being executed. At that time in the filtration of water attention was paid chiefly to the æsthetic purifying of it alone. In subsequent years all cases of failure in the efficacy of the filters are in all probability to be regarded as due to frost in hard winters. The water in the open filters freezes and the coating of ice makes it impossible to cleanse the top layers of the filtering sand, as is otherwise done at regular intervals by carefully removing the slimy layer which has been deposited on the sand and which in time stops up the pores of the filter. When a hard frost came as long as the better modern methods were unknown the authorities were obliged to use all kinds of extreme measures to make the filters pervious and very often the function of them was heavily damaged by those measures.

Here I show you two diagrams which represent the number of monthly attacks of enteric fever in Hamburg and Altona for the years 1883–85, calculated per 10,000 inhabitants. During these years we had in Hamburg different large epidemics of enteric fever which you will see occurred as a rule in autumn, if not in winter itself, and they repeatedly overlapped into the following year. Altona did not share in these epidemics, at the most only in so far as is easily explained by the close intercourse between the inhabitants of the two towns. But when the epidemic in Hamburg receded it began to increase in Altona (but much more severe, much more sudden, and rising to greater heights than in Hamburg), only to fall again very rapidly. Sometimes an epidemic would break out in Altona when none preceded it in Hamburg. This happened in the beginning of 1891 and 1892, while, *vice versâ*, there were epidemics in Hamburg which left Altona untouched—as, for example, in the autumns of 1889 and 1892. It cannot, therefore, be assumed that enteric fever always broke out in the low-lying Altona whenever Hamburg sent an unusually great number of enteric bacteria through the sewers into the Elbe. But we must conclude that the part of the Elbe running past these two towns was in a constant state of infection and that enteric fever broke out in Altona when the filters did not properly perform their functions owing to hard frost in January and February. On the other hand, outbreaks of enteric fever occurred in Hamburg when the water in the Elbe was low, in the autumn of dry years, which led to the tidal wave coming unusually far up the river, bringing with it, as far as the intake of the town waterworks, a large quantity of Elbe water polluted by enteric discharges. Such dry seasons occurred in the years 1885, 1886, 1887, and 1892; while, on the other hand, the dry season of 1883 brought with it no appreciable increase of enteric cases, for the reason that at that time an alteration of the river bed which was to shorten the path of the tidal wave was not yet completed. Only by these circumstances can we explain how it is that in these two towns, merging into one another without any definite line of demarcation, enteric fever ran such different courses. The epidemic in Hamburg, with a gradual rise and gradual fall, lasted nearly eight months; in Altona, with the exception of the winter 1887–88, the epidemic, in the form of severe explosions, lasted only one or two months and was at its height at a period several months later than in Hamburg. But in both towns the whole area of the water service was always attacked practically in the same way. From the drawing I show, which represents the state of things in the winter 1887–88, you will see how matters stood within the borders of Hamburg and Altona. On the left lies Altona territory, on the right Hamburg territory, separated by the characteristic boundary line. Below, the Elbe is indicated. Each of the 12 areas represents the state of affairs in series of monthly averages. You will see that in July, 1887, and June, 1888, at the beginning and end of the series, on both sides alike there was but little enteric fever: only from two to five cases per 10,000 inhabitants. Matters stand thus in Altona up to November, whereas in Hamburg the number of cases goes on increasing till in December it is at its height—26 per 10,000 inhabitants. Then comes the decrease, so that by March the same conditions are reached as in the preceding July. The very month Hamburg is free from enteric fever Altona is attacked most severely; likewise with 26 cases per 10,000 inhabitants, the increase in the number of cases beginning the preceding November. And exactly the same thing occurred in other winters up to 1893. Since then the central system of filtration has been introduced in Hamburg; and here, as well as in Altona, we have learnt to master the difficulties during the period of hard frost. Since that time large epidemics of enteric fever have not occurred in either town. But isolated cases of enteric fever have remained—viz., about three or four per annum per 10,000 inhabitants, from 200 to 300 cases, with, approximately, 30 deaths. Among these there may be many cases that are wrongly diagnosed as enteric fever, as diagnosis is not always very easy, and young medical men have no longer much opportunity of becoming acquainted with the disease. On the other hand, many slight cases may escape detection which are of no clinical interest and which are not recognised as enteric fever but which may nevertheless have been important factors in the spread of the disease.

Thus the number of reported cases may be approximately correct. Nearly a third of these can, as a rule, be shown to be imported, chiefly from North American ports and from small villages in the mountains or by the sea, where families go to recruit during the summer holidays, never heeding that in many of these places the sanitary conditions leave much to be desired. Another considerable series of cases can be directly traced to the Elbe; they concern skippers and boatmen on the river craft in the Elbe or workmen who work at the water side. Then we have had in some years groups of cases which, with more or less probability, could be traced to infected milk from a particular milk service or from one particular farm in the neighbourhood. Lastly, there are always cases which are obviously directly infected—for example, among sisters and brothers in small dwellings or among nurses in hospitals. After subtracting all these cases there still remain 100 or even more which cannot be traced to any known source of infection. Naturally, however, one can easily content oneself with the assumption that, considering the intercourse between the inhabitants of a large city, nothing is to be wondered at. The incubation period is from two to three weeks, so how can the person always remember how, where, or when he may possibly have exposed himself to infection or even judge whether he was in danger of infection or no; as, for example, when bathing in the Elbe, visiting such and such a house, or partaking of food and drink which, perhaps, came from a distance from an infected place, as in the case of oysters? But one may also ask oneself the question that has been asked by more than one person whether these few cases cannot be traced to the filtered Elbe water, as the filters cannot be absolutely relied upon to keep back every germ. Sometimes it appears as if the number of cases of enteric fever in the town increased after the filtered water showed for a time an increased percentage of germs, just as is believed to have been observed in London. Sometimes, however, the comparison does not hold good. In my opinion (at any rate with us) this question cannot be decided statistically because the numbers involved are too small. The matter will not be solved till we have deep well water instead of filtered Elbe water in our water mains. Decisive steps towards this alteration in the water-supply have already been taken, and in two years' time we hope to be able to supply a third of our needs with deep well water. And I do not doubt that after this is accomplished the remaining two-thirds will follow in the not too distant future. What enteric fever then remains will certainly have nothing to do with the water-supply. Already now I should like to remark that several large towns of Germany supplied with deep well water have not less enteric fever than Hamburg.

After setting forth these considerations I will here show you a diagram representing the yearly number of deaths from enteric fever, calculated per 10,000 population, since the year 1840 up to the present time. I have omitted the figures for preceding years as they are too unreliable to be of any value. The number of fatal cases, however, must be taken instead of the actual number of cases as we only know the latter since the year 1872. In this diagram you will see that since the great fire of 1842 the prevalence of the disease has steadily diminished although interrupted by great fluctuations; and, further, that since 1894 the number of cases has been very few indeed. This favourable condition of things since 1894, and the gradual sinking of the curve since 1892, can be easily understood without further statement after what I have shown you up to this point. But how are we to explain the great rising of the curve in 1857, 1865, and 1889? This is a question on which many opinions have been expressed without any completely conclusive answer being given.

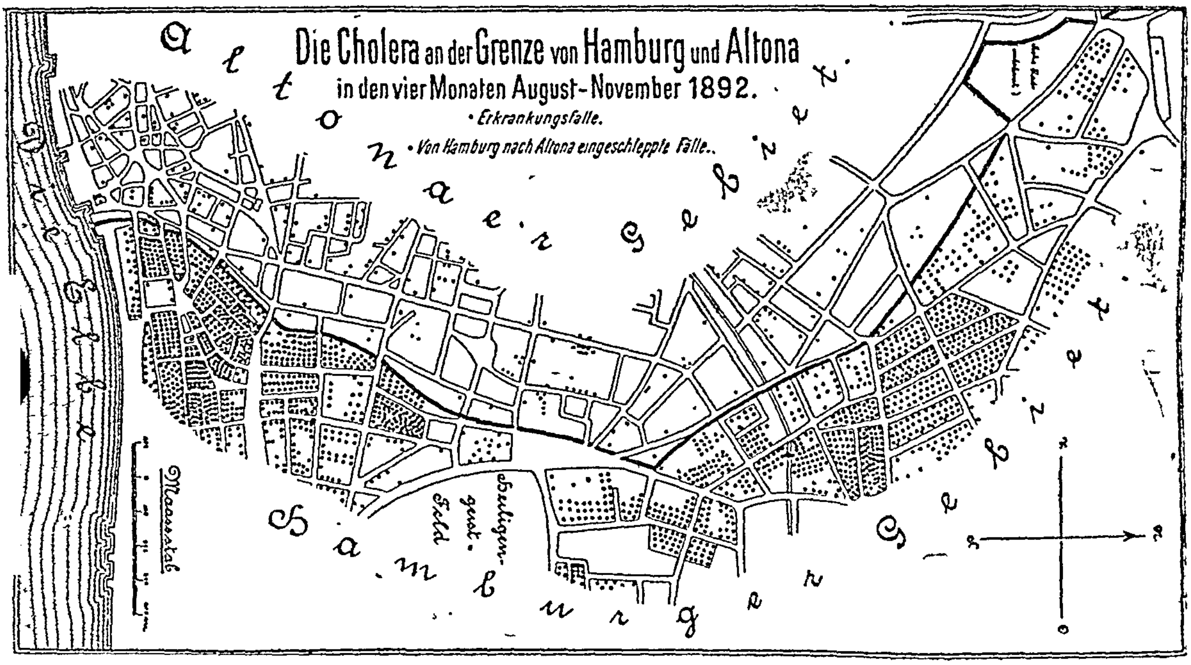
In this diagram over the columns representing the number of fatal cases of enteric fever per annum, I have given also the index of rainfall in millimetres as far as these numbers are known, and in the diagram showing the monthly cases, over the curve over the number of monthly cases, in addition to the average temperature curve, I have given the average level of the ground water for each month. Comparing the two representations you will see that the level of the ground water and rainfall are practically parallel—that is to say, that the level of the ground water is so much lower the less the rainfall is, and *vice versâ*. Further, you will see clearly that the great epidemics of enteric fever fall in dry years when there is a low level of ground water, whereas in very rainy years enteric fever obviously recedes. These observations agree in every respect with the celebrated observations of Pettenkofer of Munich. Explanation is as difficult as the facts are self-evident because the Pettenkofer explanation of facts clearly does not hold good after the importance of the part water plays in the diffusion of enteric fever, which was disputed by him, has now unquestionably been established. Most seductive of all is the assumption that dry seasons specially favour the transmission of enteric germs from the dejecta of enteric fever cases to the alimentary canal of other persons. Without entering upon many self-evident general reflections I may state that in the case of Hamburg this theory is supported by the fact that the explosive outbreaks in Altona occurred in the middle of the coldest part of the winter, a season which is usually regarded as being particularly free from enteric fever; and, further, these explosions obviously occurred because through the sudden disturbance of the process of filtration the hitherto impeded progress of the bacteria was made possible from the Elbe water (into which they had entered with the discharges of the patient by means of the sewage) to the alimentary canal of other persons. Is not the conclusion most obvious that similar mechanical circumstances also decided the course of the Hamburg epidemics? I have already tried to make this appear probable with regard to the epidemic of the "eighties" and I do not doubt but that similar mechanical circumstances—that is to say, high floods and a low level of water in the Elbe, both of which are favourable to the pollution of the water service with the contents of the sewers—had a decided influence on the epidemics of 1857 and 1865 But it is very difficult to sift such questions sufficiently thoroughly, because the average numbers referring to the monthly levels of the water of the Elbe, or the size of the flood, or the fatal cases of enteric fever, do not suffice to settle the matter. More must be known of the local spread of the disease in the town, of the different floods, and of the conditions of the stream at the time; facts which can no longer be ascertained. But the probability of the case seems to me to speak in favour of my theory, although it does not, of course, explain everything. I consider it a dangerous practice, and one to be avoided, to want to explain in a word the endless intricate workings of nature. I should like specially to emphasise the fact that dry seasons, in some way or other, seem particularly to favour infection by contact and the different indirect transmissions of infection in different houses by means of articles of food, vegetables, or flies. For in many places where periodic epidemics of enteric fever show a similarity with Hamburg there are no tidal ebb and flow and they cannot all be explained by the theory that dry years and seasons specially favour the pollution of wells. I should like to believe that in former times the latter circumstance played an important rôle, at all events in Munich. Whether, however, it can be applied in all cases, or whether altogether different circumstances do not come into consideration in the periodic outbreak of enteric fever, must remain an open question. In this respect we have still much to learn. In any case, you will see by my curves that since 1894, when the sanitary condition of Hamburg was improved, fluctuations in the rainfall and level of the ground water have no longer had any influence on the frequency of the outbreaks of enteric fever—just as is the case with Munich since the cesspools were either made impervious or done away with altogether and replaced by sewers which freed the numerous town wells from the pollution brought about by the pervious pebble subsoil from the privy pits.

And now as to cholera. Here I can express myself more shortly, as almost all that I have said about enteric fever can be applied to cholera which follows the same modes of spread as enteric fever. On nearly every occasion the disease has come to us by the same classical route that is characteristic for the whole of Germany. It spreads from Asia to Russia and then crosses the German frontier with the floating rafts travelling down the Vistula from Poland. From the Vistula it follows the navigable water-ways of the river through canals into the Oder and from this river enters the Havel and Spree again by canals and thence the Elbe. The "Oberländer" ships are always the first with us to be affected by cholera. It is only in exceptional cases that the route is a different one, as, for instance, was the case in 1892 when Hamburg was attacked before any other place in Germany. The disease then came probably by the sea route from Paris or Havre, in all probability with some ship's water ballast taken in at Havre harbour polluted by sewage. The diagram I show tells you about the outbreak of cholera in our town. The columns show the number of cases per 1000 inhabitants and the black parts the number of deaths. As you will see, the disease has visited us in Hamburg a good many times. The infection has never come to Germany without visiting us and remaining with us for a longer or shorter period. This can be easily understood from our relations to water and from the conditions of our marshes described above.

The great epidemic of 1848 was not, however, much less than that of 1832. But the sanitation of the town plays as important a part as it does in the case of enteric fever, and every succeeding epidemic has been less severe than the preceding one. In each of them the scene of action is principally on and near the water, or at least among that part of the population connected with the water. From these people the disease is spread further to other portions of the town, that is to say, to parts some distance from the water lying on the "geest" or high land, and to persons having no connexion whatever with the Elbe. Comparatively speaking Altona always escapes because its harbour is smaller and of very much less importance to the town than that of Hamburg is to the town of Hamburg, and because also the whole of the town of Altona lies high up on the "geest." When cholera does break out there it is near the Elbe. In the case of these Hamburg epidemics in former years, whether it is a fact that cholera germs also got into the water-supply cannot now be determined. It can hardly have been in any considerable degree on account of the local spread of the infection described above. On the other hand, something of the kind seems to have happened in Altona immediately after the opening of the new central water-supply in 1859. On August 4th of that year the water service was inaugurated and it is a fact that at first the filters did not properly perform their functions. Soon afterwards the largest cholera epidemic Altona has ever known, with eight cases per 1000 inhabitants, broke out, spreading over the whole town. The information at hand is too scanty to enable us to do more than to surmise. In Hamburg, where the height of the epidemic was reached in July, there were then 10·5 cases per 1000 inhabitants. In the epidemic of 1871 matters were already very much clearer. There was at that time a slight outbreak in Hamburg, beginning in August, with 0·5 case per 1000 inhabitants. A little later Altona was attacked. The first cases occurred on August 19th, after unfiltered water had been delivered by the service pipes from August 11th to 18th. But the number of deaths was three times as great as in Hamburg—namely, 1·43 per cent. as opposed to 0·43 per cent. in Hamburg. The medical authorities of Altona at the very time of the outbreak attributed this epidemic to the water service and publicly expressed their opinion.

The importance of all these earlier observations on the diffusion of cholera and enteric fever by means of the water service of the two towns was not thoroughly understood and appreciated till the great cholera epidemic of 1892 broke out in Hamburg, teaching a lesson which could no longer be misunderstood. The essential characters of this epidemic are well known to you, so I can confine myself to following a few points. There were 26·42 cases per 1000 inhabitants and 13·44 per 1000 deaths, whereas in Altona these numbers were 3 81 per 1000 and 2·13 per 1000 respectively, and in Wandsbeck still less—namely, 3·06 per 1000 and 2·09 per 1000. Among the Altona cases were a large number of persons who were infected in Hamburg. The boundaries between these two so widely differing infected areas follow closely the political boundary which, as before stated, coincides exactly with the boundary of both public water-supplies. To illustrate this fact I once more lay before you the well-known plan (Fig. 3) from Gaffky's description of the epidemic within the borders of Hamburg and Altona, in which plan appears the total number of cholera cases and deaths. At the bottom, to the east, you will see the streets of Hamburg thickly studded with cholera cases. At the top, to the west of the boundary, you will see the streets of Altona with only very few cases, a large number of which were imported from Hamburg. On the Hamburg side the whole area as far as the water service reaches was attacked simultaneously in the same way, whether it was the "geest" or marsh that was concerned, or whether the portions of the town were near to, or far from, the Elbe. This is a fact which must effectually refute the earlier theory that the marsh was attacked first by the disease, because the subsoil here consists partly of organic materials intermixed with human dejections. The marsh was attacked first in former times only because it lay nearer to the water and because the water from the polluted marsh ditches and "Wetterungen" was used for drinking purposes. Now all at once the "geest," which was scantily supplied with water and which had hitherto been almost free from the disease, was attacked as severely as the marsh because, through the water service, infected water was brought also into these more distant parts of the town, built partly on pure sand, only the year before.

FIG. 3.



Die Cholera an der Grenze von Hamburg und Altona
in den vier Monaten August-November 1892.
• Erkrankungsfälle.

Spot map, showing the distribution of cholera on the borders of Hamburg and Altona in the four months August–November, 1892.

The same circumstances explain how numerous cholera cases imported from Hamburg into the marsh districts near the Elbe gave rise to new small groups of cholera cases; whereas in the "geest" villages, provided they lay far from the river, there was no spread of the disease worth mentioning. Further, the temporal course of the epidemic too is very characteristic of the infection of the water-supply. On August 16th the first cases occurred near the Elbe; on August 21st we had about 100 cases, and on August 27th more than 1000 a day. No previous epidemic had ever been of such an explosive character, a fact which is better explained by the diagram which I now show than by any verbal description of it. The diagram represents the weekly course of the different big cholera epidemics in Hamburg, not in absolute numbers, but calculated for each week, per 1000 population, so that the different diagrams can be easily compared with one another. Not even the fairly suddenly arising epidemic of 1848 can be compared with the short, stormy course of that in 1892. This epidemic, which attacked 16,850 persons and killed 8576, was followed in 1893 by another smaller outbreak, which could again be traced to the water service. The water was filtered by this time, but under pressure of circumstances the year before the work had been hastily brought to a termination and set in operation. It was therefore possible that unfiltered Elbe water from without entered the conduit conveying the filtered water from the filters to the pump and mingled with the filtered water. It was not till some days had elapsed that the damage was discovered and the matter immediately put right. But it had sufficed once more to introduce cholera bacteria into the town, although fortunately only in small numbers. 202 persons were attacked and 60 of them died. Since then Hamburg, like the whole of Europe, has been free from cholera. Should the disease reappear, epidemics such as we have had in the past are out of the question, provided very unusual and improbable circumstances in connexion with the waterworks do not arise. But after what I have told you about enteric fever we shall never feel quite secure against cholera. For Hamburg's close connexion with the river, the navigation, and the numerous small water-courses, offer enteric fever and cholera only too many opportunities of introducing themselves into the town. We shall, however, be better able to cope with a case of cholera than with isolated cases of enteric fever, because as a rule diagnosis is easier and the incubation period much shorter and because it is easier (during the short months of the danger from cholera, which occurs for some months' duration every ten years or less) to direct the attention on this one point than to carefully observe year by year every isolated case of enteric fever.

That, gentlemen, is roughly the epidemiology of enteric fever and cholera in Hamburg, considering each disease separately. What relation do they bear to one another? Past experience has already taught us that enteric fever and cholera epidemics repeatedly coincide with one another, which is not to be wondered at in face of the great similarity of their modes of spread. Not only do both seek out similar localities in which insanitary conditions exist in connexion with the excrement disposal and the water-supply, not only are both associated in their spread with water, but also dry years and dry seasons with low level of subsoil water are favourable to the development of both diseases. It must, therefore, necessarily follow that when cholera breaks out in a locality enteric fever, which is usually indigenous there, seizes the same opportunity for further development. In Hamburg it has been repeatedly observed what a peculiar interest attaches to those years in which both diseases were disseminated simultaneously side by side throughout the town by means of the water-supply. At those times enteric fever broke out from two to three weeks later than cholera, corresponding to the different lengths of the period of incubation. This was established conclusively in 1892 and 1893. And a similar connexion exists also between these two diseases and choleraic diarrhœa. Choleraic diarrhœa, together with other causes, is brought on after a very short incubation period by drinking water polluted with sewage. In this connexion the best-known example is the illness caused by the consumption of oysters which have come from oyster-beds situated in the neighbourhood of town sewage outfalls. Some persons are attacked by choleraic diarrhœa soon after eating infected oysters, others fall victims to enteric fever a fortnight or three weeks afterwards, and some suffer from both. Dr. Bulstrode, in a very carefully written report, has lately described such occurrences at Winchester and Southampton. We ourselves made a similar observation in 1893. A great shipbuilder's yard supplied its workmen with Elbe water purified in a filter-bed of its own. At the beginning of August the whole of the filtering material was taken out, cleansed, and put back again. In so doing the filter was rendered very inefficient. A few days later over 100 workmen fell ill with choleraic diarrhœa in a more or less violent form, and after some time in 19 of the persons pronounced enteric fever developed. In the same way it can be explained how it is that in the more recent great enteric fever and cholera epidemics in Hamburg, which have been more narrowly observed, there has always been a large number of infants who died from choleraic diarrhœa who certainly suffered neither from cholera nor enteric fever, and that since the introduction of a central system of filtration of the drinking water in Hamburg a decrease of from 1000 to 2000 deaths occurred annually among infants. Although at present we do not know the origin of choleraic diarrhœa, nevertheless, according to these observations, it is certain that in association with the unboiled water used for diluting the milk or for washing out the milk-pans it gets into the intestine of the child and here develops its harmful action. We have also some observations from Berlin, from the district of the Stralaus waterworks, between the years 1886 and 1893, showing that every time the number of germs in the water-supply increased to an abnormal extent the number of deaths among infants increased in the same proportion.

Thus in the war which we have been waging against cholera and enteric fever, we have, by the introduction of a purer water-supply, at the same time overcome a third enemy—viz., choleraic diarrhœa. Here, gentlemen, I come to the end of my dissertation, which has left untouched many important aspects in the epidemiology of enteric fever and cholera, and in which I have been obliged to avoid all numerical statistics. However, I hope that the few points which I have brought forward have proved of interest to you and have been welcome as a contribution to the studies to which your society has dedicated itself.

THREE CASES OF RENO-RENAL REFLEX PAIN:

CASES IN WHICH THE SYMPTOM POINTED TO THE SOUND KIDNEY BEING THE DISEASED ONE.

BY DAVID NEWMAN, M D., F.F.P.S. GLASG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

SPONTANEOUS pain is an important symptom of renal disease when the outflow from the pelvis is in any way interfered with, and probably in no organ of the body is the suffering more acute and more varied in character than in some of the maladies affecting the kidney and the ureters. During an attack of renal colic the pain generally extends over a wide area, involving most of the abdomen and back. But while widely distributed it is generally most severe on the affected side, between the level of the tenth rib and the crest of the ilium. Its character and situation vary according to circumstances and may often guide the surgeon in forming an opinion as to the nature of the lesion giving rise to the suffering. When obstruction to the ureter is present the pain may extend down the thigh to the knee, involving all the pain areas from the tenth dorsal to the second lumbar, whereas when a stone is impacted in the kidney it will cause little suffering when the patient is at rest but when he exerts himself or is submitted to sudden jolting, pain is developed in the ninth and tenth dorsal areas. The feeling may only amount to a sense of uneasiness or discomfort, it may be a dull or gnawing pain, it may be very acute at times or may reach to a degree to be described as lacerating torture, accompanied by agonising spasms The suffering may be of short duration, with intervals of complete freedom from pain, or it may be persistent. The less severe pains, as a rule, continue steadily in their course and are located in one place, while the more acute pains are generally remittent and extend over considerable and constantly varying areas. Dull persistent pain in most cases indicates a slow, steady change in the condition and bulk of the renal parenchyma or in the size of the pelvis, as is seen in tuberculous nephritis and in tumours; on the other hand, acute suffering is due to lesions which suddenly interfere with the exit of urine from the pelvis—for example, in calculus, in tuberculous pyelitis, or ureteritis, or in obstruction from the impaction of a blood clot. When the pain is acute it is not always referred to the seat of the disease but may cause spasm of the bladder, pain in the testicle, at the point of the penis, in the hip joint, down the thighs, or the suffering may be limited to the kidney on the opposite side to the one that is the seat of the disease.

This reno-renal reflex pain has been described by Guyon and Thornton and considerable importance has been attached to it by these writers; while, on the other hand, Morris in his recently published book on "Surgical Diseases of the Kidney and Ureter"[1] says: "It is important to know that a stone in one kidney will sometimes excite sympathetic pain and irritation in the other; but this transferred or sympathetic pain is of an aching character, not of a spasmodic or colicky description, is only occasional, and never occurs except as an accompaniment of more severe pain on the affected side. So far as my own experience and researches go, there is not a single case which affords satisfactory evidence of symptoms on one side only being caused by a stone in the kidney of the other side. The presence of a stone in the painless kidney is not proof that the painful opposite organ is not also affected. That the attacks on the painful side have ceased after removing a calculus from the painless kidney is not conclusive; this may be nothing more than a coincidence, due either to the accidental shifting of a calculus in the painful kidney, or to the calculus becoming lodged in some immovable manner. There may be very advanced disease of the kidney on the painful side and a symptomless calculus in the opposite kidney. In a case which has been under my care of late there was a sarcomatous growth in the right kidney with hæmaturia, but an entire absence of pain and tumour on the right side throughout the whole course of the disease; yet intense pain was experienced in the left renal region radiating over the left side only. The inference would have been that this was a typical case of reno-renal reflex pain had not symptoms during the last few weeks of life and a post-mortem examination shown that the left-sided pain was due to a similar new growth involving the left transverse processes and the left side of the bodies of the lower dorsal vertebræ. I consider the doctrine of reno-renal reflex with an absence of pain in the affected kidney as unproved and unsound and if acted upon in practice likely to lead to very serious and dangerous results."

---

[1] Surgical Diseases of the Kidney and Ureter, vol. ii., p. 84.

In a communication which I published in the *Glasgow Medical Journal* [2] I tried to show that my experience led me to believe that reno-renal reflex pain is a fact which must be accepted and in proof of my opinion I cited the following cases, one under the care of Mr. A. E. Maylard, a second published by Mr. Edmund Owen, and a third which was under my own care, and in addition to those I have three others which demonstrated beyond doubt that reno-renal reflex pain is a fact which must be accepted. The following is from the article in the *Glasgow Medical Journal*:—

W. I., æt. 58, consulted me on the 25th May, 1899, with a history of dull pains in the left lumbar region during the last seven years and of acute attacks of renal colic at intervals of from two to three months. These attacks were usually brought on by active exercise or by driving and were accompanied or succeeded by hæmaturia, which usually lasted for some days after the pain passed away. The patient was sent into the "Central Home" for examination during one of these attacks and on exploration with the cystoscope blood was seen to flow from the *right ureter only*. This was observed on several occasions. I therefore advised exploration of the right kidney but the patient was so convinced that the disease was on the left side that he would not consent to an operation being done.

Mr. A. E. Maylard has kindly given me the following account of a somewhat similar case which came under his observation:—

D. M., aged 38, had complained for six months of a "nagging" sort of pain in the right iliac region which seemed to him to pass upwards and lodge in his right lumbar region where it produced a dull, sickening sensation. It would linger there for 24 hours, causing him during the time to vomit and making him at the end of the attack feel very weak. He had four bad attacks of acute iliac and lumbar pain. Immediately after one of these attacks the urine was found to contain a quantity of albumin, red blood cells, but no tube-casts. In the course of a few days the urine returned to the normal. Frequency of micturition was never a symptom.

Believing the case to be one of renal or ureteral calculus on the right side the kidney was explored and a ureteral catheter passed from the pelvis of the kidney. Nothing was, however, detected. The patient had complete suppression of urine after the operation which continued till his death on the fourth day.

The kidneys, examined after death, showed the right one—previously explored by operation—to be healthy and the left to contain a calculus about the size of a pea in one of the upper calyces (March 6th, 1901).

A very interesting case is reported by Mr. Edmund Owen (*British Medical Journal*, June 8th, 1901, p. 1385), in which the pain was limited to the right side. The right kidney was explored with a negative result and at a subsequent operation a large phosphate calculus (400 grains) was removed from the left kidney. Commenting upon the case the author remarks: "I am well aware that it is not a very unusual occurrence for a surgeon to operate upon the wrong kidney in his search for a stone; but I do not think that a more conspicuous instance than this of [illegible] jective symptom of *pain* in renal cal[illegible]. Subjective signs are [illegible] range of surgery; but in the [illegible] kidneys which have drawn their nerves blindfold from the epigastric pool it is small wonder if, in the absence of objective signs, patient and surgeon are sometimes led by them to make mistakes."

CASE 1. *Pain [illegible]ulating renal colic on the left side of five years' [illegible]ion, other symptoms and signs pointing to calculu[illegible] the right kidney; stone removed from the right [illegible].*—A woman, aged 25 years, consulted me in [illegible]0, complaining of severe pain in the left [illegible]gion which had been present more or less since [illegible] The attacks of renal colic lasted, as a rule, from [illegible] to nine hours and were associated with suppression of urine. In the more prolonged attacks the pain extended over the whole abdomen and back, but the area of greatest intensity was in the left lumbar region. The pain generally subsided suddenly and was followed [illegible]ious excretion of dilute urine. Physical examination [illegible] abdomen was difficult on account of the [illegible] unusually stout for her age and muscular [illegible] very marked during an attack of colic, but [illegible] the attacks nor in the intervals could [illegible]ng be detected and pressure over the two organs failed to reveal greater tenderness over the one than over the other. Prior to consulting me the patient sought advice from a surgeon in London who came to the conclusion that she was suffering from a calculus in the left kidney and advised an operation for its removal. At the onset of the illness the attacks of renal colic seldom occurred oftener than once in two or three months, but by midsummer, 1902, she was seldom free from gnawing pain in the lumbar region and the attacks of renal colic were more frequent, sometimes as often as once a week, and associated with occasional hæmaturiæ. In the intervals between the attacks no abnormal constituent could be found in the urine with the exception of occasional slight deposits of pus, but during the attacks of hæmaturia blood was found to escape from the right ureter only. No tubercle bacilli could be found. Cystoscopic examination revealed nothing abnormal in the bladder with the exception that the mucous membrane around the right ureteral orifice was unduly injected and the lips of the orifice were ragged and projecting into the bladder. A ureter catheter was passed and also an examination was made by sounding the ureters with a resonator probe. Neither from the catheterisation nor from the sounding was any definite information acquired but the cystoscope showed the kidney from which the blood was flowing. While the pain pointed to the presence of a stone in the left kidney the appearance of the bladder and the circumstance that blood flowed from the right ureter only indicated the disease to be on the right side. Repeated endeavours were made to detect the presence of a stone in the right kidney by means of Roentgen ray photography and after four futile attempts a successful photograph was obtained[3] (Fig. 1). On Sept. 3rd, 1902, I performed a nephrolithotomy on the right kidney and removed a stone of about the size of a marble from the pelvis. The kidney was situated unusually high up and hence considerable difficulty was experienced in extracting the stone. The patient made a good recovery and since the operation there has been no recurrence of pain in either renal region, nor has there been any hæmaturia.

CASE 2. *Symptoms of renal calculus on the right side of over 18 months' duration; x rays detected stones in the left kidney which were removed; disappearance of pain on the right side.*—The following note I received from Dr. Thomas Colvin:—

A married man, aged 33 years, first consulted me in April, 1902, in regard to an aching sensation across the lumbar region and over both

[3] The Roentgen-ray photographs were done by Mr. J. Trotter, 28, Gordon-street, Glasgow.

[illegible] n nor did his urine seem to [illegible] ntity. He was daily at his [illegible] ing over the region described [illegible] an actual pain. On examination I found his temperature and pulse normal. The urine to the naked eye did not suggest hæmaturia or pyuria but on testing it was found to contain a small quantity of albumin. My diagnosis was subacute nephritis and I prescribed rest and the usual routine treatment for that complaint. He made a good recovery although a trace of albumin was present in his urine when he returned to business again. A year later, in April, 1903, he again consulted me and this time he complained of pain across the lumbar region and especially in the right loin. There was not the shadow of a doubt of the pain at this time being on the right side and not on the left side. [illegible] mination was made. The question was now raised of a renal calculus on the right side, and an operation was even hinted at, but as the patient seemed to improve rapidly with absolute rest in bed, a milk dietary, and diuretics and was most anxious to return to business nothing further was done. Two months later, on June 2nd, he sent for me hurriedly one morning and said that several times during the previous night he had had acute attacks of pain on the right side over his right kidney and shooting down towards his right testicle. According to his description of these attacks they suggested to my mind renal colic, although not of such an agonising character as is often seen. His urine again contained blood. I then told him that there was no doubt that he had a calculus or calculi in the right kidney and insisted on his seeing Dr. Newman in regard to an operation. He consulted him a few days later and an operation on the right side was recommended. The patient had fortunately for himself as the sequel showed, a strong objection to operative interference, so he sought the waters of Harrogate in the hope of a cure. Whilst there he consulted a physician in Harrogate who also recommended an operation on the right side. On the advice of a friend he went to London and consulted a surgeon who wrote to me that my patient had most probably right pyelitis due to calculi and he recommended operation on the right side. It is only fair to say here that the patient told the consultant that he had been cystoscopically examined and skiagraphed with no definite result. The remaining history of the case will be related by Dr. Newman. I have only to add that the case was a most instructive one to me [illegible] deeply impressed on my min[illegible] renal diagnosis. I am firmly [illegible] to any medical man with the symptoms I have mentioned his advice would have been to operate on the right side. There was only one other point. Was the right kidney normal? To that question my [illegible] on [illegible] was [illegible] dis[illegible] hall [illegible]

When I was asked to see the patient on May 4th, 1903, I came to the conclusion that he was suffering from a calculus in the right kidney but to confirm the diagnosis I had an x-ray photograph taken and on the 11th I examined the bladder with the cystoscope. From neither of those observations was any benefit derived. The bladder was strictly healthy and there was nothing remarkable about the appearance of the orifice of either ureter and the photograph failed to show any distinct shadow of a calculus. On August 7th three photographs were taken and in one of them there was a faint indication of a shadow corresponding to the position of the pelvis of the left kidney, but as this was indistinct no reliance was placed upon it. Again on Oct. 12th other three photographs were taken and in two of them the same shadow was found (Fig. 2). This pointed clearly to the presence of a calculus and notwithstanding the predominance of pain upon the right side I concluded that the stone was in the left kidney. At this time there was some pus in the urine and on making a cystoscopic examination I found that it proceeded from the left kidney. This corroborated the view of the position of the calculus. On Oct. 17th I explored the left kidney and found two stones, each weighing about two drachms. The patient made a good recovery, as indicated in Dr. Colvin's report.

CASE 3. *Pyonephrosis limited to the right kidney; pus and albumin in the urine; pain most marked in left lumbar region; nephrotomy; cure.*—A man, aged 26 years, consulted me first in July, 1898. He then complained of pain across the back and extending downwards to the crest of the ilium. The history of the case showed that the first departure from health was noticed two and a half years previously. At first the pain was generally distributed over the lumbar regions on both sides. As the disease advanced the pain was most marked in the region of the left kidney and frequently limited to that part. The patient was admitted to the Central Home where on examination I found that on palpation there was a distinct enlargement of the right kidney while the left kidney could hardly be felt. On admission the patient complained of frequent micturition; the urine was copious, pale in colour, contained a considerable deposit of pus, the reaction was acid, and the specific gravity was 1010, but no blood had ever been observed nor had he passed gravel or stones. A cystoscopic examination showed the pus to be escaping from the right ureter only and this was confirmed by two subsequent examinations. The patient was advised to have an operation performed but he preferred to wait and to test the effect of complete rest and medicinal treatment for three months. In November I saw the patient again and he then told me that little benefit had been derived from the treatment prescribed and he was now anxious to have an operation performed. During the last three months the pain was almost always referred to the left renal region but as the patient was convinced by the swelling on the right side that it was the right kidney that was diseased he consented to have an exploratory incision made. On Nov. 15th I incised the kidney and evacuated ten ounces of pus but no stone was found. The patient made a good recovery and when I heard from him last from Cape Town, South Africa, he reported that there was no recurrence of the pain and that the pus had disappeared from the urine entirely (October, 1902).

Reduced x-ray photograph from Case 2 The arrow points to the shadow of the calculi.

ON SOME FORMS OF PSEUDO-APPENDICITIS (ENTERO-TYPHLO-COLITIS.—INTESTINAL LITHIASIS).

BY DR. BOTTENTUIT,
CONSULTING PHYSICIAN AT PLOMBIÈRES.

THE frequent occurrence of appendicitis and the consternation it causes both to physician and patient has led Mr. A. H Tubby to remark that as soon as a subject is seized with pain in the right abdominal region "it might be safely said that their brain is no longer in their cranial cavity but in the right iliac fossa, for so fixed is their attention on that region that every ache and pain there, any delayed action of the bowels, prompts them to expect an attack of appendicitis and to make their lives a burden to themselves and others." This prejudice has seized upon the medical faculty. For a long time appendicitis has been overlooked. How often has it been mistaken for hepatic or nephritic colic, salpingitis, &c.? It is necessary to dispel this fascination for McBurney's spot. To me it appears of [illegible] my patient's health. The first of these causes is the most important, for in many cases the degree of tension is a matter over which the surgeon has but little control; wounds the edges of which *must* be brought together can at times only be dealt with by the use of such tension as is incompatible with the life of the area of tissue involved. Thus, in a case of radical operation for the cure of an umbilical hernia where a considerable amount of tissue has been removed, each deep stitch will have between the two stitch-holes and the incision two small areas of anæmic tissue, triangular in shape, which will gradually undergo necrotic change, the stitch becoming loose as a consequence. It is easily seen, therefore, that at the end of a week or ten days the deep stitches are no longer of any service—indeed, they but serve by their irritating presence to prevent the healthy absorption of this small necrotic area and to add to the chances of sinus formation, especially when such materials as silk or salmon gut are used. Where edges come together easily and without tension such trouble may never arise unless the stitch becomes secondarily infected through the patient's own blood stream. The second cause has reference chiefly to the "mattress" suture, than which I believe there are few things in the way of a suture more detrimental to the deeper tissues of the body where tension has to be considered. This is well shown in the skin if we take the amputated breast as an example, for even where the greatest tension is necessary to bring the margins into apposition sloughing is rarely extensive or serious if a simple straight suture is employed, but when the "mattress" suture is used one frequently sees the square areas included in the stitch sloughing badly, the portion of the stitch lying parallel to the incision having cut off nearly the entire blood-supply. If, then, such suture be applied to the deep tissues the result is the same, but in addition the irritation caused by the continued presence of the buried stitch becomes a potent factor for evil. Of the third cause we know but little; indeed, at times stitches are returned almost as they were introduced without any appreciable change having taken place in the patient's bodily health to account for the occurrence. A case will illustrate this.

In April, 1901, I had occasion to perform an exploratory laparotomy on a woman, aged 50 years, for an obscure mass in the right hypochondriac region. The patient was in perfect health at the time of operation and has remained so ever since. The incision was four inches in length and in the right semilunar line and was closed in three layers, silk being used for the peritoneum and muscular wall, and no tension being caused. The wound healed by primary union throughout and the patient was discharged in three weeks. At the end of 12 months she returned with a small sinus in the scar, from which I removed two silk stitches of the muscular layer. The sinus closed at once and I heard nothing further from the patient till April of this year when she returned with a second sinus, from which I removed the continuous peritoneal suture hardly altered by its two years' incarceration.

The above case appealed to me strongly as one in which an unavoidable cause had been at work, and being one of three cases all much of the same character I turned to the question of removeable deep sutures in search of a remedy, for although there are surgeons who maintain that no stitch sinus ought ever to occur I venture to submit that such an ideal state has not yet been arrived at nor will such be attained till we can close our wounds by some method as yet unknown which requires no suture of any sort. And in the meantime, whether right or wrong in practice, we can obviate a source of great discomfort and much inconvenience, and at times pain to many patients, by the use of a suture which can be removed when its object in the tissues has been accomplished.

Having tried and abandoned many forms of removeable deep suture and come to the conclusion that none of them answer their purpose in every respect, each having some drawback, I have been led to evolve the following method which I think will be found to give satisfaction, since it combines the chief points of an ideal suture—viz., (1) it is easily applied; (2) it is painlessly and easily removed, no matter how tightly it may have been applied (thus avoiding one of the great drawbacks to sutures which depend on the lock-stitch principle when used in situations where tension is unavoidable; and (3) accurate apposition of the edges of a wound can be assured without the danger of the suture slipping, as is so often the case where the continuous lock stitch is used. The suture itself may consist of any material from fine silver wire to stout silkworm gut, but for cleanliness and ease of application I personally always use the latter, for since it is necessary that removeable deep sutures, no matter by what method they are applied, must emerge on the skin surface, silk, which from the nature of its structure rather favours by capillary attraction the entrance into the wound of micro-organisms, is to be avoided. Such an event should, however, never occur if proper precautions have been observed prior to operation. That my suture has the drawback which pertains to all removeable deep sutures—namely, that it must emerge on the surface of the skin—is inevitable; beyond this, however, it will, I think, be found to be one of the most practical at present described. Two lengths of silkworm gut are joined end to end by very fine loops without the use of knots (Fig. 1).[1] One is the suture (*a g*) and the other is the extractor (*f*). The unlooped end of the former is threaded on a needle in a handle and passed through a good thickness of tissue on each side of the wound *e*; the needle is unthreaded and the end *g* is passed through the loop *a*. The noose thus formed is drawn tight and is caught by the assistant with a fine pair of forceps (*c*) close to the loop *a* (Fig. 2). An aneurysm needle is now threaded and the end *g* being drawn well through the eye the needle is passed beneath the stitch *a*, *b* and then through the loop *h* which is thus formed. The suture being now caught by the finger and thumb at the point *k* (Fig. 3) the needle is withdrawn. By pulling on the loop *k* a knot is made round this loop and round the loop *a* which will hold the suture. The end of a stout piece of silkworm gut (*m*) (Fig. 4) is now passed through the loop *k* which is drawn down upon it gently; this serves to prevent any tendency on the part of the loop to slip during its sojourn in the wound, since it acts the part of a lock suture. As each of the deep sutures is completed this same piece of gut is passed in this manner and so serves for all. The free ends of the extractors (*f*) and of the sutures (*g*) are threaded on a needle, each pair in turn, and are brought through the skin about an inch from the wound and *on the same side of it as that from which the suture was passed*; a knot is made on the extractor to distinguish it, and a split shot is fixed to both. The free ends of the lock suture are brought through the skin beyond each end of the incision and are similarly shotted. The wound is then closed and dressed in the usual manner. When it is considered desirable to remove the deep sutures all that is necessary is to remove one of the shots on the lock suture *m* and to withdraw it. The remaining shots are removed and the ends *g* are each pulled upon in turn till the loop *k* is felt to disengage, after which they are cut off as short as possible by pressing the skin down while

the ends are firmly held. It will now be found that when the extractors (*f*) are firmly pulled upon the remaining portion of the suture will come away without difficulty. Should this, however, not be the case the extractor may be left in position for a day or two longer when it will be easily removed. With regard to the peritoneal suture in laparotomy wounds, although trouble may be caused at times, as in the case I have mentioned, such an event is extremely rare when very fine silk or catgut is used. I have not therefore found it necessary to depart from the ordinary form of suture. It is the sutures of the muscular and fascial layers which so commonly cause sinus formation and it is to those that the above method more especially applies. If, however, it is desired to employ a removeable peritoneal suture it may be done by the method devised by Milton[2] which is admirably suited to the purpose. In conclusion, I may say that I have submitted my method to practical test in cases of abdominal section and hernia, both femoral and inguinal, and have found it to answer the purpose well.

THE MENTAL STATE IN MYXŒDEMA.

BY H. WOLSELEY-LEWIS, M.D. BRUX., F.R.C.S. ENG.,
SENIOR ASSISTANT MEDICAL OFFICER AT BANSTEAD ASYLUM.

HAVING recently had some cases of myxœdema under my care I have had an opportunity of making the following analysis of their mental state. These patients are commonly sent to asylums as cases of dementia or melancholia. They present, however, few of the characteristics of either condition. Their memory for remote events is generally good and their impairment of memory for recent ones is slight and confined to a period coincident with the duration of their disorder. Their apprehension is fair, their coherence of thought is good, their reasoning power is sound, and their consciousness is clear. What depression they exhibit arises rather from a consciousness of their condition than from any more fundamental affection of the emotions.

It will appear that the essential change in these patients lies in a deficient power of energising their motor cells. They complain that they are languid and tired and tell of the immense effort it is to them to make even the simplest movement. This explains why they sit expressionless and in the same attitude for hours like an artist's lay figure. While, their perceptive faculties are fairly acute and enable them to gauge their relations with the world with considerable accuracy, their power of giving out their ideas to the world is minimised almost to extinction. Perception is usually good but there is no doubt that they do suffer from illusions and hallucinations at times. These abnormal perceptions are not a prominent symptom and are often of the kind known as "pseudo-hallucinations"—that is, they are not objectively very real but are simply a vivid re-perception of a "memory image." One patient thought that she heard her dead husband's voice; this, however, she explained, must really have been the voice of the man in the next room because she noticed that she never fancied such a thing when he was *away at his work, thereby showing her powers of observation* and reasoning. Another patient, thinking much about her husband to whom she was attached, would sometimes seem to hear his voice Consciousness seems to be clear as a rule. Patients recognise their disability and are worried by it. This accounts for their occasional irritability and perhaps for the rare attacks of spitefulness and even violence that have been noticed. They are anxious to do their work and may be depressed because they cannot rouse themselves to do it. Apprehension is impaired to the extent that those memory associations which are required to complete any percept need a more powerful stimulus to bring them into consciousness Hence spontaneous attention, or the instinctive selection of some stimuli in preference to others, is defective, although voluntary attention or the concentration on certain stimuli by an effort of will is good. A patient declares that, while she will sit staring vacantly before her thinking of nothing properly, she is able by an effort of will to follow some particular train of thought with as much lucidity as ever. With some stuporous cases of *insanity*, if one suddenly shouts in the ear there is no indication that they perceive the unusual stimulus, but in myxœdema it is found that the patient has been mentally "startled" though he may give little or no expression to the fact.

Memory as regards retentiveness is good but the impressibility of memory during the myxœdematous state is diminished. Hence these patients do not recall many smaller events which occur while they are in this condition but can recall with accuracy those larger events of which they took full cognisance at the time. A patient was able to give me many details of things happening some years ago and to recite with much circumstance events occurring since her recovery, but her recollection of the time during which she was ill was imperfect. Some writers state that myxœdema extending over some time leads to a permanent dementia. I have had two patients, both of whom had a relapse of the disease due to ceasing to take thyroid extract, who exhibited little dementia after recovering a second time, though the whole disease extended in one case over seven years.

---

[2] THE LANCET, June 6th, 1903, p. 1585.

Ideation and the formation of concepts do not appear to be diminished and the association of ideas seems to be good. There is a retardation of thought and the elaboration of an idea is difficult but complete. These patients are coherent and their speech, though slow, is to the point. In a recovering patient one of the earlier signs of improvement was that she began to read novels and she now assures me that she could picture to herself the scenes described therein as well as ever and that she found no difficulty in the understanding and amplifying of such abstract ideas as "speed" and "thought."

Judgment and reasoning power are not defective and once aroused to attention the myxœdematous subject can give a very sound opinion. Thus, I asked a patient, Would you prefer working half an hour every day in the week for 1*d* a day or four hours on one day for 7*d.* and why? She answered that she would work half an hour on each day because she would then gain 7*d.* for three and a half hours' work. It took her five minutes to answer this question but she told me that she had made up her mind long before that but could not get the answer out. On inquiry she explained that she felt the answer "on the tip of her tongue" but failed to voice it. As far as I have observed these patients have no definite delusions but they are inclined to be suspicious. The capacity for work is diminished and they are conscious that their mental processes are less facile and that they readily tire. They cannot follow an argument closely for long and have to put down the book they are reading sooner than when they are well. These patients neither laugh nor cry and any sign of emotion is rare with them. Their affective state, however, is not one of indifference, the maternal instinct is strong, and they usually retain their consideration for others and affection for their relatives. Their sensitiveness is not decreased, for one of my patients having almost entirely lost her hair I chaffed her good-humouredly about it; this I afterwards found she had felt acutely and when she recovered was able to recall the feeling of shame which had suffered. Their moral sense is in no way blunted. h these patients are often described as melancholiacs , do not appear to be more depressed than is natural as the result of the consciousness of their condition.

It is essentially in disturbances of volition and action that the peculiar mental symptoms of this condition manifest themselves. A diminution of volitional impulse produces that lack of initiative, that striking immobility of face and body so characteristic of the disease. To originate even the simplest movement requires a very special exercise of the will. An external stimulus to produce a movement must be unusually strong. It is at the commencement of action that the block occurs and noticeably when once action has begun it flows more easily. The execution of the movement itself is slower than usual. Patients describe the tremendous difficulty they had, not in perception or understanding but in action. A loud command elicits a quite inadequate response though their appreciation of the order seems in no way diminished. It is noticeable that these patients are always more "tired" in the morning than in the evening. One tells me that if "a neighbour popped in to see her" it did her good, because at first she could hardly answer a word but after a time found she conversed more easily. Another was asked to get up from her chair, to walk to the end of the ward, to sit down on another chair, and to return (the whole manœuvre in a healthy person taking 30 seconds). It took her three minutes to do this, half the time being occupied in getting up from her chair, so that one wondered whether she had understood the request; she informed me afterwards, however, that she had the greatest difficulty in making a start but that once on the move she could get along fairly easily. To make a simple statement, "Yes" or "No," took a patient five seconds but she always answered correctly; to make a complicated movement such as "clasping the hands behind the back' took 45 seconds. Under treatment these times gradually shortened coequally with quickening of the pulse and rising of the temperature. On admission it took a patient five seconds to say what part of her face I touched; after 14 days' treatment it took her two seconds. I have not found that, apart from their slowness, the movements made were particularly clumsy, these patients when getting better often writing and sewing nicely. I noted in one patient that the knee-jerk, though well marked, was delayed and the contraction of the quadriceps extensor was prolonged.

I submit then that the changes in the mental condition of those suffering from myxœdema are almost confined to the sphere of action. It seems necessary to suppose that either some toxin in the plasma surrounding the motor cells inhibits the chemical processes which originate a motor impulse or that the absence of some substance from the blood interferes with the discharge. This toxin is neutralised or this essential substance is supplied by the administration of thyroid extract; the patients get well and keep so as long as they continue to take thyroid. I have observed that the simultaneous exhibition of syrupus ferri iodidi appears to assist its action. We see this class of patients described by such terms as dull, listless, apathetic, taking a long time to comprehend and to answer questions, of sluggish ideation, of sluggish mentation, demented, depressed, moping, lethargic, suspicious, of impaired memory, sleepy, torpid, contented, and irritable. I suggest that this proves on careful inquiry to be but part of the truth and that the majority of these cases are sent to an asylum in error and could be as well treated outside one.

A CASE OF ULCERATIVE COLITIS IN WHICH A LEFT INGUINAL COLOTOMY WAS PERFORMED TO CONTROL EXTENSIVE HÆMORRHAGE.

By HENRY BETHAM ROBINSON, M.D., M.S.Lond., F.R.C.S Eng.,

SURGEON TO OUT-PATIENTS AT ST. THOMAS'S HOSPITAL; SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL, ETC.

The following case was operated on by me as long ago as May, 1891, and, death occurring a few days after, I exhibited the diseased colon as a card specimen at the Pathological Society of London and a brief account appears in vol. xlii. of the Transactions, p. 115. As reference to this case by subsequent writers[1] and inquiry by others as to further details have been made to me from time to time, I have thought it desirable to record the case in full. It has been referred to as one of the earliest cases, if not the first, in which the colon has been opened for this ulceration. Mr. A. W. Mayo Robson[2] records a case operated on by him in June, 1891, in which a left inguinal colotomy was performed so as to treat locally the diseased mucous membrane through the artificial anus. Now, in my case the motive was the attempted arrest of a dangerous and exhausting hæmorrhage assumed to have its origin in the sigmoid loop which was tender and unduly palpable. The diagnosis was correct and the purpose was effected, but owing to the feeble condition of the patient he died on the fourth day before there was any opportunity of considering the advantages to be obtained from direct treatment of the ulcerating mucous membrane. This, then, is the explanation why the colon in this case was exposed on the left side, a form of treatment, from the light of our later experience, giving a much lessened chance of effectually dealing with the disease than when the opening is in the neighbourhood of the cæcum.

A man, aged 66 years, was admitted into St. Thomas's Hospital for cataract extraction in the early part of April, 1891. For some months he had been in a state of debility but with no definite symptoms except that about a month before admission he had passed blood per rectum and from time to time had had pain about the left iliac region; he had never been out of England. On admission he was cachectic-looking and his urine was slightly albuminous. About three weeks afterwards (May 2nd) he had diffuse abdominal pain, not very acute, and there was no marked tenderness, except in the

---

[2] Mayo Robson: Ibid., vol. xxvi., p. 213.

left iliac region, where there was some increased resistance over the line of the colon. There had been constipation for two or three days, so the bowels were relieved by an enema, a well-formed motion being followed by an acute diarrhœa with plenty of mucus and bright blood. The above symptoms were accompanied by vomiting which occurred several times. The free hæmorrhage from the bowel continuing through the day, the condition of the patient became such that it was imperative to do something to stop it. As stated before there were some fulness and increased resistance in the left iliac fossa with tenderness; no actual tumour was to be made out here or elsewhere in the abdomen. These signs with the bright blood pointed to the part of the bowel involved—namely, the sigmoid flexure, and it was evident that some large vessel was opened. The diagnosis rested between malignant disease and ulceration of the colon and the signs in general suggested that it was the latter condition. I decided to open the abdomen in the left inguinal region so as to explore the sigmoid flexure and to control the bleeding spot.

An incision three inches long was made, the muscle was divided, and the parietal peritoneum was fixed to the skin margin. The sigmoid loop was drawn out and the cause of the hæmorrhage was fortunately discovered. There was a large ulcer about two inches by one inch in the long axis of the bowel and along its free edge; the base of the ulcer appeared to be practically only peritoneum. *As it seemed certain that* this ulcer would perforate this segment of the gut was brought up out of the wound and fixed there by passing a glass rod through the mesosigmoid and packing it round with gauze. The bowel was not opened. There was no further pain or hæmorrhage and the patient took his fluid nourishment well. On May 7th in the early morning the *bowel opened spontaneously at the site of the ulcer; during* the day he was not so well, getting gradually more feeble, and he succumbed during the night.

At the post-mortem examination there was found well-marked ulcerative colitis beginning in the cæcum and extending to the lower end of the sigmoid flexure where the changes were most marked. Here the bowel was thickened and contracted, showing many small circular sharply cut ulcers as well as the one large ulcer before mentioned; many of these were evidently of long duration. The rectum was practically healthy. Under the microscope the bowel gave no evidence of malignant disease. Very marked granular contracted kidneys were present.

Upper Wimpole-street, W.

A CASE OF ANEURYSM OF THE AORTA RUPTURING INTO THE PULMONARY ARTERY ASSOCIATED WITH FIBROSIS OF ONE LUNG.

BY FREDERICK J. SMITH, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN AND PATHOLOGIST TO THE LONDON HOSPITAL.

(*With a Note on the Lung by* Dr. R. N. SALAMAN, *Acting Director of the Pathological Institute, London Hospital.*)

THE following case seems sufficiently rare to merit publication. The patient was a soldier, aged 31 years, sent to me by Dr. Alexander of Bromley on Jan. 26th, 1904, on account of shortness of breath and some swelling of the right side of the neck and face; he also complained of a cough and pain in the back. For the following notes I am indebted to my house physician, Dr. H. E. Ridewood. Of the patient's family history nothing need be said. His personal history was that he had been a soldier for many years in India and had had there gonorrhœa with bubo and gleet but had no recollection of syphilis, though it was obviously possible if not probable. He had malaria in 1895 and recently—up to three or four months previously—had been working as a labourer. He drank moderately. The history of his present illness was that he was well enough up to some three or four months ago, when he began to complain of a cough and of shortness of breath. Both these symptoms had gradually but steadily and progressively got worse; he also complained that they were worse in the morning after lying down and *occasionally had caused a distinct feeling as though he* would choke. On one or two occasions lately they had actually caused a fainting attack. In addition to these symptoms he had (1) a dull aching pain starting from the right side of the root of the neck radiating upwards into the head, worse at night and on coughing; (2) swelling of the right side of the neck, face, and shoulder, which was worse on lying down; and (3) difficulty in swallowing, all three of which had, like the other symptoms, gradually increased in the last three months.

On admission the patient was a thick-set muscular man of
medium height, very obviousl
culty of breathing associated

upper part of the right chest and neck. He was not at all wasted nor cachectic nor, indeed, feeling very ill in himself and had walked up to the hospital and to the ward unaided. His temperature was normal. Examination of his chest gave the following physical signs. Over the swollen area the veins were more obvious to the eye than on the corresponding parts of the left side but they did not pulsate and would not fill from the cardiac side. The swelling itself was doughy but without any pitting on pressure anywhere. He had perceived it himself because he could no longer wear his usual 16½ inch collars. His breathing, which he himself described as shortness of breath, was very typically—so much so that I used him for clinical demonstration of the point—that due to some form of laryngeal obstruction with slight stridor on inspiration, more marked on slight exertion or on lying flat on his back in bed. The cough was dry and brassy in character and the respirations were 40 per minute.

Palpation enabled us to fix the heart's apex beat just above the sixth left rib five inches from the mid-sternal line. The general cardiac impulse was slightly heaving *as though the organ were somewhat hypertrophied.* On percussion the cardiac dulness was practically normal, extending from the apex in a slanting direction inward to the junction of the third rib with the sternum and bounded by the left border of the sternum. There was an area dull to percussion over the first and second right ribs and the intercostal space between them and extending over the upper part of the sternum even to the first intercostal space on the left side. Auscultation of the heart revealed the following condition. *At the apex the sounds were clear and somewhat* exaggerated, at the base the second aortic was slightly

this was, I think, merely a conduction of the tracheal sound; otherwise there was nothing unusual except an occasional rhonchus and a few crepitations at either apex. In view of the post-mortem changes it must be distinctly noted that I could not remember any noticeable difference in the breath sounds on the two sides except *the ordinary normal louder* sounds on the right.

Features external to the chest.—Tracheal tugging was looked for and my house physician thought he could appreciate it but I was unable to do so; he also states that it became more marked in the course of time. The pulse was 84 per minute, of medium tension; the vessel wall was palpable on rolling it under the finger but could not be styled very degenerate. There was no appreciable difference in time or volume between the two radial pulses. The carotids could not be compared owing to the swelling of the neck. The pupils were equal and active for accommodation and to light. There was no paralysis of either vocal cord. To account for the pain in the back nothing could be seen, felt, or heard; an occasional pain down nearly to the wrist on the right arm seemed to own a causation in common with the swelling. The blood, urine, and abdominal organs were all carefully examined but showed nothing pathological. There was some dysphagia which had recently become more marked. The only other point that seems to call for notice was one which Dr. Alexander communicated to me but which I did not notice in hospital, that the left side of the face would swell if he lay on his left side.

The patient was treated with morphine, iodide of potassium, &c., but the treatment presents no features of interest except that he may be said to have improved somewhat. On Feb. 3rd, 1904, he seemed as well as usual. On the 4th he asked for the nightstool but did not use it, for he was at this moment seized with an attack of coughing and then suddenly complained of an acute
cardiac region, his face and lips became

pulse at the wrist disappeared, his respirations became rapid, from 60 to 70 per minute, and the stridor mentioned earlier disappeared. Dr. Ridewood was opportunely in the ward and saw him at once; he noticed the above points and naturally thought the aneurysm had ruptured into some natural sac; he examined him as carefully as the condition would allow and noted that there was no sign of fluid in either pleura nor was there any alteration in the pulmonary physical signs. There was no increase in the area of cardiac dulness, the heart was acting regularly and quietly, about 85 per minute, and the sounds were quite clear and well heard, contrasting, as he remarks, strongly with the absence of radial pulse. No bruit was heard, the patient did not vomit, there was no hæmoptysis, in fact, the above points—pallor, rapid breathing, and absent pulse—were the only indications of some accident. He remained for some time without change and then the respirations became of a sighing character and he died as nearly as possible two hours after the pain suddenly seized him.

Necropsy.—Post-mortem examination revealed an aneurysm of the ascending and transverse arch of the aorta of about the size of a small orange which had ruptured into the pulmonary artery; the ruptured aperture was large enough to admit the tip of the little finger and was situated about an inch or rather more from the pulmonary valve well on the heart side of the bifurcation of the pulmonary artery; the edges of the rupture were evidently fresh. This aneurysm showed no laminated clot; it did not involve the aortic valves; these were quite sound as far as ordinary appearance would show; it reached backwards so as to press upon the bifurcation of the trachea, thus explaining the dyspnœa and dysphagia. On the posterior surface of the abdominal aorta was a second aneurysm just opposite the origin of the cœliac axis; this was of about the size of a hen's egg, typically sacculated, and filled with laminated clot; it had eroded the vertebral column, making for itself a nest as it were; this cleared up satisfactorily the pain in the back, though it had given no other indication of its presence. The heart was slightly larger than usual but showed no other pathological condition to the naked eye; the valves were healthy. The spleen weighed 17 ounces and was very adherent to the diaphragm. The liver weighed 74 ounces and was adherent to the diaphragm. The kidneys were practically healthy. Of the lungs, the right was slightly œdematous and showed a small patch of tiny subpleural ecchymoses; these without close scrutiny might have escaped observation and except for them there was not the slightest trace of any unusual ante-mortem changes in the circulation through either lung. This was particularly noticed owing to the nature of the accident that had caused death. The left lung was in a peculiar condition of fibrosis (there was no trace of this in the right one). I am indebted to Dr. Salaman, acting director of the pathological institute of the London Hospital, for the following careful description of it which adds greatly to the interest of the case.

Note by Dr. SALAMAN.—The left lung was firmly adherent to the chest wall; the pleura was thickened, especially along a line corresponding to the necks of the ribs behind. The fibrous tissue of the thickened pleura did not extend into the lung tissue. The bronchial glands were not enlarged and except for some anthracosis were normal. On section the whole lung tissue, although aerated throughout, was found to be uniformly dense and fibrotic; the fibrous tissue was to the naked eye more obvious at the root of the lung and along the track of the bronchi. There was no caseation nor puckered scar anywhere.

Microscopical examination of the tissues at the root as well as of those along the free margin of the lung showed a very definite fibrosis of the alveolar tissue brought about by granulation tissue in the septa and alveolar walls which had spread in from the large collection of older granulation of fibrous tissue accumulated around the bronchi and vessels. In many places, both in sections of the lung at the root and at the free margin, groups of condensed granulation tissue were met in which were numerous large giant cells sometimes surrounded by definite epithelioid cells and sometimes by more dense fibrous tissue. The giant cells were mostly very large and contained some 20 or more peripherally arranged nuclei. Some giant cells were smaller but they also contained a large number of nuclei. 18 preparations were most carefully searched for tubercle bacilli without success. In the younger granulation tissue at the periphery of the older nodules there were very many alveoli inclosed which, although possessing no lumina, still were lined by well-preserved cells whilst occasionally the appearances strongly suggested a new formation of epithelial tubular structures—such an apparent or real formation I have noticed in an undoubted specimen of syphilitic lung disease. In no section was there any sign of caseous degeneration. The blood-vessels, except for the marked periarteritis, were normal.

The result of the macroscopic and microscopic investigation tends to the view that the cirrhosis of the lung is syphilitic in origin; such a change in the lung in acquired syphilis is of the greatest rarity, and it is interesting to note that the condition was present in one lung only. The morbid change is very different from the one observed in congenital syphilis where both lungs are uniformly involved and the cirrhosis is not essentially bronchial or vascular in its distribution.

Note by Dr. SMITH.—Aneurysms of the aorta bursting into the pulmonary artery seem to be very rare. Ziegler mentions the incident as occasionally occurring but I could nowhere find a detailed account of the symptoms arising from it, which must be my excuse for a somewhat prolix account of the present case. Dr. G. Newton Pitt informs me that he has met with a case which lived for three weeks after communication had been established and in which a secondary aneurysm arose in the pulmonary artery. It is to be hoped that he will place the case on record. In my case, judging by the absence of pulse at the wrist, aortic blood pressure must have very rapidly sunk to the level of that in the pulmonary artery and death must have ensued from imperfect distribution of blood to the brain which was rapidly starved. Speculation on this point is more of physiological than clinical interest.

Harley-street, W.

THE TREATMENT OF HYPERTROPHIC PHARYNGITIS AND LARYNGITIS BY THE EMANATIONS FROM THORIUM NITRATE.

BY J. GORDON SHARP, M.D. EDIN.

IN October, 1902, I attended a man, aged 36 years, in an attack of left-sided pleurisy with a small amount of effusion which cleared up in six weeks' time without tapping and caused no subsequent trouble. During this period he had persistent cough and brought up small quantities of white frothy mucus. This was examined by a competent authority on one occasion but no tubercle bacillus could be found. The patient had only lost some four or five pounds in weight Despite the negative bacteriological result the case was suggestive of tubercle. He spoke in a husky tone and complained of "weakness in his voice" when he talked much. This huskiness had existed for ten years, he said, and at the time of its onset he sought advice for the trouble at Guy's Hospital and stated that he was there treated with cod-liver oil emulsion but could give no more definite information on the subject.

As soon as the man was able to come to my house I examined the nose, pharynx, larynx, and neighbouring parts. There was nothing of note wrong in the nose but the soft palate and pillars were studded with yellowish tubercles in size rather less than the dimensions of a pin's head and set in a red mucous membrane. These tubercles were not enlarged lymph follicles but might have passed for the bodies seen in miliary tuberculosis of the pharynx. When the tongue was pulled forward the lingual tonsil was seen to be much hypertrophied. The back wall of the pharynx presented the usual appearances of a chronic inflammation and the epiglottis was red and enlarged. The interarytenoid region was infiltrated with dark red tissue and here also could be seen the same yellow bodies found on the soft palate. No ulcer was detected. The ventricular bands were swollen, extending so far towards the middle line as to prevent the vocal cords being seen. Here also were to be seen one or two yellow tubercles. As may be expected there was a chink between the true cords on account of the interarytenoid swelling. All the parts, including the interior of the larynx, were covered by a whitish, sticky secretion. To come to an exact diagnosis of the pathological condition was a matter of great difficulty.

Although there was absence of pallor and of ulceration I was inclined to look upon it as tuberculous laryngitis of the indurative type. On the other hand, the case presented some of the features of lupus. For a long time I regarded the condition as tuberculous of very slow growth and others who saw the case regarded it in the same light and as such I treated it. However, a lengthened experience of it leads me to the view that it is chronic inflammatory which may at any time take on a tuberculous character. If I am to fit it into a class I shall call the laryngeal affection hypertrophic laryngitis (pachydermia diffusa) although I have difficulty in explaining the presence of the yellow tubercles.

Treatment.—Assuming then that the affection was tuberculous the treatment was (1) general by generous dietary and cod-liver oil, and (2) local by the application of glacial acetic acid to the soft palate, pillars, and the glottis, beginning with a 10 per cent. solution twice a week and gradually increasing to full Pharmacopœial strength in six weeks' time. For two months the full strength acid was applied twice weekly, making a three and a half months' trial of the acid twice a week. During the next three months the full strength acid was applied on six occasions only and at varying intervals of time. Probably had I looked upon it as simply inflammatory applications other than glacial acetic acid might have been employed with greater benefit.

Result of glacial acetic acid treatment.—The yellow tubercles had almost all disappeared from the soft palate and pillars and there was some loss of tissue. The infiltration in the interarytenoid region had become less and the swelling of the ventricular bands had considerably diminished and a partial view of the true cords could be obtained. On the whole there was great improvement, although the condition was far from well. The hypertrophy of the lingual tonsil caused no annoyance and was not treated. The man's general condition was unchanged. There was no chest trouble and he was able to follow his employment but had often to go to bed at night as soon as he had had his supper—in short, he was easily tired out. It looked as if no further benefit could be obtained from the acetic acid and I lost sight of the patient for some months.

Treatment by the emanations from thorium nitrate solution.—On Jan. 23rd, 1904, the patient again called to see me and on examination I found the parts much as I have described and I decided to try the effect of emanations from neutral thorium nitrate soluti [illegible] inhale [illegible] fitted [illegible] and added to it 100 grammes (about three and a half ounces) of neutral thorium nitrate and shook till the salt was dissolved. The man was instructed to inhale for one hour every day and always at the same time of the day and he was told to keep a daily record of any pain or discomfort which he might experience during the exercise. He began on Jan. 24th and inhaled for one hour daily for a month with two or three exceptions when he had to curtail the time or to desist altogether on account of "aching of the throat." On one occasion his report reads: "Throat and chest very sore indeed." Gradually he got accustomed to the treatment and experienced no inconvenience. At the end of a month I examined the parts and found a decided improvement and told him to go on with the inhalations for another fortnight, making six weeks in all. I again examined the pharynx and larynx and the first thing that impressed me was the healthy condition of the back wall of the pharynx. This part had received no direct treatment when the acid was being applied to the palate and glottis To resume, the pharyngeal wall was covered with [illegible] had so far returned to their normal state as to enable me to see the vocal cords. It will be interesting to watch the further progress of this case. I have the impression that tubercle will ultimately develop.

Are the good results due to the emanations from the thorium? To this question I am not going to give a positive answer but I feel encouraged to give the treatment further trial and I hope others will be led to adopt this comparatively new line of therapeutics.

Leeds.

◆

THE USE OF MUCOUS MEMBRANE FROM FROG'S MOUTH FOR GRAFTING IN A CASE OF SYMBLEPHARON.

By LESLIE PATON, B.A., M.B CANTAB., F.R.C.S. ENG.,
ASSISTANT OPHTHALMIC SURGEON, ST. MARY'S HOSPITAL.

THE patient, a man, aged 31 years, was admitted into St. Mary's Hospital in June, 1903, suffering from orbital cellulitis. There was marked exophthalmos with great œdema of the lids and surrounding tissues On operation a considerable quantity of pus was let out and the orbital tissues were freely drained by means of four tubes. At the time of operation some of the ocular muscles on the upper and outer parts of the eye were exposed and were seen to be of a dirty brownish colour. The cellulitis subsided uneventfully and in about a month he was discharged from the hospital. At the time of leaving the lid tissues and the conjunctiva were hypertrophied and the lower lid was attached firmly to the eyeball in almost its whole extent, only a space of about three millimetres being free at the outer canthus and about two millimetres from the punctum at the inner angle. At those points a probe could be passed down for a short distance but it could not be passed laterally in either direction. The line of attachment touched the lower margin of the cornea. The lashes seemed to have been destroyed completely. By September the hypertrophy had completely subsided and the upper lid was normal in appearance. Owing to the complete attachment of the lower lid to the eyeball, however, there was very great limitation of movement and there was diplopia in every movement, so that the right eye had to be covered constantly.

The patient was admitted again in September for operation. It was obvious that a large amount of mucous membrane would be necessary to form a conjunctival sac for his lower lid and I came to the conclusion to try whether the membrane from the roof of a frog's mouth would be suitable. Three frogs were used and from these three flaps were prepared, the largest being about two centimetres in length by one centimetre in breadth; the other two, from smaller frogs, were approximately the same breadth but shorter. These were kept in warm sterilised saline solution while the eye was prepared In dissecting the surfaces care was taken to leave any normal conjunctiva attached to the ocular surface. The dissection was carried down until over a centimetre of raw palpebral surface was exposed. To this the larger piece of mucous membrane was attached by four fine silk sutures along the upper margin, the lower margin being left unattached. The other two pieces of mucous membrane were similarly sewn to the fringe of conjunctiva on the ocular surface They were carefully arranged in position and a piece of green protective was pushed in and the eye was closed and bandaged. On the sixth day the protective was taken out and the stitches were removed. All three grafts had taken, the palpebral one and the outer ocular one perfectly, the inner ocular one not quite so well, and at the line of its suture there was a fleshy granulation. The movements of the eye were now free except that on extreme movement outward there was some diplopia.

At the time of writing (March, 1904) the appearance of the eye is almost normal. There is an irregularity of the lower lid margin which, however, is not marked. On pulling down the lower lid at [illegible] cicatricial band passing to the [illegible] three millime [illegible], almost normal in appear- [illegible] the outward movement of [illegible] the right eye to some extent and I propose to do a further slight operation to free that. I believe that frog's skin has been used frequently for skin grafting. The above case shows that where extensive mucous membrane pulse at the wrist disappeared, his respirations became rapid, from 60 to 70 per minute, and the stridor mentioned earlier disappeared. Dr. Ridewood was opportunely in the ward and saw him at once; he noticed the above points and naturally thought the aneurysm had ruptured into some natural sac; he examined him as carefully as the condition would allow and noted that there was no sign of fluid in either pleura nor was there any alteration in the pulmonary physical signs. There was no increase in the area of cardiac dulness, the heart was acting regularly and quietly, about 85 per minute, and the sounds were quite clear and well heard, contrasting, as he remarks, strongly with the absence of radial pulse. No bruit was heard, the patient did not vomit, there was no hæmoptysis, in fact, the above points—pallor, rapid breathing, and absent pulse—were the only indications of some accident. He remained for some time without change and then the respirations became of a sighing character and he died as nearly as possible two hours after the pain suddenly seized him.

Necropsy.—Post-mortem examination revealed an aneurysm of the ascending and transverse arch of the aorta of about the size of a small orange which had ruptured into the pulmonary artery; the ruptured aperture was large enough to admit the tip of the little finger and was situated about an inch or rather more from the pulmonary valve well on the heart side of the bifurcation of the pulmonary artery; the edges of the rupture were evidently fresh. This aneurysm showed no laminated clot; it did not involve the aortic valves; these were quite sound as far as ordinary appearance would show; it reached backwards so as to press upon the bifurcation of the trachea, thus explaining the dyspnœa and dysphagia. On the posterior surface of the abdominal aorta was a second aneurysm just opposite the origin of the cœliac axis; this was of about the size of a hen's egg, typically sacculated, and filled with laminated clot; it had eroded the vertebral column, making for itself a nest as it were; this cleared up satisfactorily the pain in the back, though it had given no other indication of its presence. The heart was slightly larger than usual but showed no other pathological condition to the naked eye; the valves were healthy. The spleen weighed 17 ounces and was very adherent to the diaphragm. The liver weighed 74 ounces and was adherent to the diaphragm. The kidneys were practically healthy. Of the lungs, the right was slightly œdematous and showed a small patch of tiny subpleural ecchymoses; these without close scrutiny might have escaped observation and except for them there was not the slightest trace of any unusual antemortem changes in the circulation through either lung. This was particularly noticed owing to the nature of the accident that had caused death. The left lung was in a peculiar condition of fibrosis (there was no trace of this in the right one). I am indebted to Dr. Salaman, acting director of the pathological institute of the London Hospital, for the following careful description of it which adds greatly to the interest of the case.

Note by Dr. SALAMAN.—The left lung was firmly adherent to the chest wall; the pleura was thickened, especially along a line corresponding to the necks of the ribs behind. The fibrous tissue of the thickened pleura did not extend into the lung tissue. The bronchial glands were not enlarged and except for some anthracosis were normal. On section the whole lung tissue, although aerated throughout, was found to be uniformly dense and fibrotic; the fibrous tissue was to the naked eye more obvious at the root of the lung and along the track of the bronchi. There was no caseation nor puckered scar anywhere.

Microscopical examination of the tissues at the root as well as of those along the free margin of the lung showed a very definite fibrosis of the alveolar tissue brought about by granulation tissue in the septa and alveolar walls which had spread in from the large collection of older granulation of fibrous tissue accumulated around the bronchi and vessels. In many places, both in sections of the lung at the root and at the free margin, groups of condensed granulation tissue were met in which were numerous large giant cells sometimes surrounded by definite epithelioid cells and sometimes by more dense fibrous tissue. The giant cells were mostly very large and contained some 20 or more peripherally arranged nuclei. Some giant cells were smaller but they also contained a large number of nuclei. 28 preparations were most carefully searched for tubercle bacilli without success. In the younger granulation tissue at the periphery of the older nodules there were very many alveoli inclosed which, although possessing no lumina, still were lined by well-preserved cells whilst occasionally the appearances strongly suggested a new formation of epithelial tubular structures—such an apparent or real formation I have noticed in an undoubted specimen of syphilitic lung disease. In no section was there any sign of caseous degeneration. The blood-vessels, except for the marked periarteritis, were normal.

The result of the macroscopic and microscopic investigation tends to the view that the cirrhosis of the lung is syphilitic in origin; such a change in the lung in acquired syphilis is of the greatest rarity, and it is interesting to note that the condition was present in one lung only. The morbid change is very different from the one observed in congenital syphilis where both lungs are uniformly involved and the cirrhosis is not essentially bronchial or vascular in its distribution.

Note by Dr. SMITH.—Aneurysms of the aorta bursting into the pulmonary artery seem to be very rare. Ziegler mentions the incident as occasionally occurring but I could nowhere find a detailed account of the symptoms arising from it, which must be my excuse for a somewhat prolix account of the present case. Dr. G. Newton Pitt informs me that he has met with a case which lived for three weeks after communication had been established and in which a secondary aneurysm arose in the pulmonary artery. It is to be hoped that he will place the case on record. In my case, judging by the absence of pulse at the wrist, aortic blood pressure must have very rapidly sunk to the level of that in the pulmonary artery and death must have ensued from imperfect distribution of blood to the brain which was rapidly starved. Speculation on this point is more of physiological than clinical interest.

Harley-street, W.

THE TREATMENT OF HYPERTROPHIC PHARYNGITIS AND LARYNGITIS BY THE EMANATIONS FROM THORIUM NITRATE.

BY J. GORDON SHARP, M.D. EDIN.

IN October, 1902, I attended a man, aged 36 years, in an attack of left-sided pleurisy with a small amount of effusion which cleared up in six weeks' time without tapping and caused no subsequent trouble. During this period he had persistent cough and brought up small quantities of white frothy mucus. This was examined by a competent authority on one occasion but no tubercle bacillus could be found. The patient had only lost some four or five pounds in weight Despite the negative bacteriological result the case was suggestive of tubercle. He spoke in a husky tone and complained of "weakness in his voice" when he talked much. This huskiness had existed for ten years, he said, and at the time of its onset he sought advice for the trouble at Guy's Hospital and stated that he was there treated with cod-liver oil emulsion but could give no more definite information on the subject.

As soon as the man was able to come to my house I examined the nose, pharynx, larynx, and neighbouring parts. There was nothing of note wrong in the nose but the soft palate and pillars were studded with yellowish tubercles in size rather less than the dimensions of a pin's head and set in a red mucous membrane. These tubercles were not enlarged lymph follicles but might have passed for the bodies seen in miliary tuberculosis of the pharynx. When the tongue was pulled forward the lingual tonsil was seen to be much hypertrophied. The back wall of the pharynx presented the usual appearances of a chronic inflammation and the epiglottis was red and enlarged. The interarytenoid region was infiltrated with dark red tissue and here also could be seen the same yellow bodies found on the soft palate. No ulcer was detected. The ventricular bands were swollen, extending so far towards the middle line as to prevent the vocal cords being seen. Here also were to be seen one or two yellow tubercles. As may be expected there was a chink between the true cords on account of the interarytenoid swelling. All the parts, including the interior of the larynx, were covered by a whitish, sticky secretion. To come to an exact diagnosis of the pathological condition was a matter of great difficulty.

previously. He was not struck but in his haste to get away from the police he was knocked down in the rush and trampled on. He was arrested as a gambler, conveyed to the police station, and as he complained of some abdominal pain he was taken to hospital after a two hours' journey from the New Territory. He was a badly nourished narrow-chested youth, about 90 pounds in weight.

On admission his temperature was normal; the pulse was 120 and good. The abdomen was slightly tympanitic in front and in the flanks; some gurgling was felt on pressure. The patient was put to bed and spent a good night. Lead and opium fomentations were applied to the abdomen. On the following morning his bowels were opened twice with an enema. The temperature was 98·2° F., the pulse was 120 and improved, and as he had not passed urine during the morning ten ounces were drawn off with a catheter. The abdomen still remained tympanitic all over; change of position made no difference.

It was decided to watch the case. There was no shock; the patient was chatting with his neighbours and would have sat up in bed if allowed. Fomentations to the abdomen were continued and the diet consisted of milk, beef-tea, and rice-water. At 8 P.M. the temperature reached 100°, the abdomen was more distended, and the pulse was not improving, so it was decided to make an exploratory incision as it was suspected that the spleen was ruptured. At 9 P.M. Dr. W. V. M. Koch kindly administered chloroform and with the assistance of Mr. J. Bell the abdomen was opened with a two-inch incision midway between the pubes and the umbilicus. A gush of blood followed the opening of the peritoneum and distended coils of small intestine filled the wound. The incision was rapidly prolonged upwards to the left of the umbilicus and the spleen was examined. It was a large one of the malarial type and a rupture was easily felt at the posterior border. The pedicle was ligatured with strong silk and a spleen weighing 2 pounds 3¼ ounces was removed. The peritoneal cavity was quickly cleansed of blood, filled with saline solution, and the abdominal wound was closed. An injection of 15 minims of strychnine was given hypodermically after the operation. The patient passed a good night and appeared to be recovering from shock. Morphine, strychnine, and camphor were given hypodermically at intervals. The temperature was 97° and the pulse was 130. He felt inclined to vomit. At 9 30 P.M. he vomited once, bringing up some brownish "coffee-ground" vomit. The pulse was then 142 and thready and the temperature was 100°. Nutrient enemata were given every six hours and retained. Champagne only was given by the mouth.

On Jan. 24th the temperature was normal and the pulse was 120. The patient conversed with the Chinese ward boys. He vomited frequently during the night, "coffee ground" vomit on each occasion. Towards evening he seemed to be improving rapidly; he only vomited once during the day. He took a little milk by the mouth and retained it. The nutrient enemata were partially returned. The vomit examined microscopically showed altered blood corpuscles and blood pigment. The patient, in spite of steady improvement during the day, gradually sank during the night and died at 10 45 A.M. on the 25th.

Necropsy.—Post mortem examination showed that the pedicle ligature had held well; there was no sign of even commencing peritonitis. The stomach was much distended and full of brown fluid and its mucous membrane was dotted with minute petechiæ, like flea-bites. The contents of the stomach consisted of altered blood and gastric secretion. The intestines and their contents were normal. All the other organs were healthy.

Remarks by MR. LAING.—My reason for recording this case is that it is of interest from both a surgical and medico legal point of view. Undoubtedly the patient's death was due to persistent hæmatemesis following abdominal section. Such cases are undoubtedly rare and a few have, I believe, been recorded, but I am not able just now to quote them in detail. Why petechial hæmorrhage should begin after abdominal section in an otherwise healthy stomach I am unable to determine. No injury was done to that organ when removing the spleen, as it was easily displaced upwards for the purpose. The patient recovered well from the shock of the operation and it was naturally a disappointment to lose such a case from such a cause.

That a man can live with little or no discomfort for 26 hours with a ruptured spleen is of considerable medico-legal interest. Had the police not arrested the patient I daresay he would not have had any medical or surgical attention whatever but would have bolted for his native village and have died in due course. The rupture was one of three inches long, just through the capsule, so that the hæmorrhage was slow but sure. The accompanying tympanites made the diagnosis difficult even here where ruptured spleens are fairly common and have been removed successfully.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

On the Value of a Comparative Examination of the Blood and Urine.—The Bacteriological Findings in a Case of Climatic Bubo.—A Case of Bacillus Pyocyaneus Pyæmia following Ear Disease.

A MEETING of this society was held on April 19th, Dr. E. KLEIN, Vice-President, being in the chair.

Dr. A. E. WRIGHT read a paper on the Comparative Examination of the Blood and Urine. He said that his communication was to illustrate the practical use of a method which he and Dr. J. Newport Kilner had recently described and published in THE LANCET for estimating the amount of salt in the blood and the amount of salt in the urine.[1] He first described the method by which he estimated the quantity of salt in the blood and in the urine. He said that in judging of the efficiency of the kidney there were two points to consider: (1) the capacity of the kidney to eliminate salt from the blood; and (2) the capacity of the kidney to eliminate water from the blood. He had found in a case of urticaria in which there was a considerable quantity of albumin in the urine that the excretory efficiency of the kidney for salt was practically normal and at the same time he found that the coagulation period of the blood was prolonged to five minutes and that the lime salts were diminished. He therefore concluded that the albumin in the urine was due to a serous hæmorrhage into the kidney and not to structural disease of the organ. He pointed out that a diminished quantity of lime salts in the blood produced a diminished coagulability and such a diminution of lime salts was brought about by the introduction of soaps, sour alcohol, sour fruit, and gooseberries, and this accounted for the production of urticaria after the ingestion of these articles. Dr. Wright mentioned the case of a boy with physiological albuminuria in whom the excretory quotient for salt was normal, and he stated that in all cases of renal disease he had found the excretory quotient of salt to be less than normal.

Mr. J. CANTLIE and Dr. R. T. HEWLETT described the Bacteriological Findings in a case of Climatic Bubo. Mr. Cantlie said that the climatic bubo was probably a form of plague or pestis minor. He had seen numerous cases in 1893 and the disease usually appeared before plague and continued during and after that disease had stopped. It attacked the white race in particular. It was a definite disease which ran its course with fever in from three to four weeks. The glands enlarged and had to be excised. They contained several foci of necrosis with but little pus. The disease could not be arrested by early excision of the glands; in fact, it was best to wait for two or three weeks before excising them. Mr. Cantlie distinguished between pestis minor and pestis ambulans, for in the latter the definite plague bacillus could be found. Mr. Cantlie and Dr. Hewlett then described the results of a bacteriological examination of the case of climatic bubo. The patient, who had come from Kolar Goldfields, had a condition of the inguinal glands which was seen by several acquainted with the disease who all agreed that it was one of climatic bubo. A gland was excised and examined. Two species of cocci were obtained (probably micrococcus pyogenes albus and micrococcus cereus albus) and also a minute bacillus. This was somewhat like the plague bacillus but perhaps rather more pointed and about half the size. It stained well by Gram's method but indifferently with the ordinary aniline dyes, with a tendency to polar staining. It was probably feebly motile and did not form spores. On agar it formed an extremely delicate growth, resembling that of the pneumococcus. It grew on gelatin very slowly, forming a white growth without liquefaction. On serum at 37° C. the growth was much more luxuriant, forming colonies like those of the diphtheria bacillus but whiter in colour.

---

[1] THE LANCET, April 2nd, 1904, p. 921.

Milk was curdled in three or four days. Glucose was feebly attacked with the formation of a little acid and gas but lactose did not appear to be attacked. Broth became slightly turbid but the major part of the growth sank to the bottom. The bacillus was without action on mice and guinea-pigs and was not agglutinated by the patient's blood. Whether this bacillus had anything to do with the disease or not must be left an open question. The chief interest in connexion with it was that it agreed in its characters very closely with the description of a bacillus isolated by Kitasato in plague.[2]—Dr. Klein said that he hoped on the next occasion that Mr. Cantlie had an opportunity he would examine the glands so as to show how the organism was distributed within them. He said that there was considerable variation in the organism described by Kitasato and it was difficult to conceive how two organisms so essentially different as the plague bacillus and the Kitasato bacillus could be varieties of the plague bacillus.—Dr. W. J. R Simpson said that he had met with a bacillus similar to that described in certain cases and had not infrequently seen the disease in Cape Town. In a cat infected with plague this bacillus was found and the man to whom the cat belonged was also affected with plague but to a mild degree. Exactly the same organism was found in the glands removed. This form of bubo seemed always to occur some time before the onset of true plague.—Dr. Wright said that he did not think that this bacillus should be considered as a variety of the plague bacillus. There was but one plague bacillus. In the present case Mr. Cantlie and Dr. Hewlett had described two forms of micrococcus and this small (Kitasato) bacillus, and it was not proved that the enlargement of the glands was due to this organism. He did not think that there was any evidence that pestis minor could develop into plague.—Dr. W. D'E. Emery said that an organism having similar characters had been obtained from acne and skin lesions and suggested that in the present case it might have had a similar origin.

Dr. T. J. Horder described a case of Bacillus Pyocyaneus Pyæmia following Ear Disease The bacillus pyocyaneus might be pathogenic to man as the partial or sole cause of abscesses, as setting up a form of dysentery, or as (rarely) causing a general infection. The case recorded was one of these last. The patient was a man suffering from otitis media of long duration. He was admitted to hospital for fever, severe headache, and delirium. Diarrhœa set in a week later. There were no signs of cerebral disease. Widal's test was twice negative and there was a leucocytosis of 32,000. Emaciation was very marked. The fever was not high but was continued in type. During the fifth week of the patient's illness paraplegia appeared. Death occurred at the end of this week. At the post mortem examination the brain and the membranes were natural. Green pus was found in both middle ears, in several abscesses in the lungs, and in a large abscess of the spinal meninges. From this pus the bacillus pyocyaneus was grown in pure culture, pathogenic to animals and giving the usual cultural reactions of this organism.—Dr. W. Bulloch said that it was possible that the general infection might have taken place after death from the point of infection in the ears. He had frequently seen spastic paraplegia come on in the course of bacillus pyocyaneus poisoning but he had no explanation of the disease. It was extraordinary that the bacillus pyocyaneus was not more pathogenic to man as it was so markedly pathogenic to animals.—Mr. L. S. Dudgeon said that he had seen two cases of bacillus pyocyaneus infection; in one of the cases he had been able to find the organism in the blood during life.

LIVERPOOL MEDICAL INSTITUTION.

Carcinoma of the Œsophagus: Gastrostomy.—Excision of the Gasserian Ganglion.—The Technique of Aseptic Surgery.

A meeting of this society was held on April 14th, Dr. James Barr the President, being in the chair.

Dr. Philip Nelson related a case of Carcinoma of the Œsophagus which occurred in a woman 50 years of age Difficulty in swallowing had only existed for three months but had rapidly increased. Her voice was hoarse and there had been several attacks of laryngeal spasm. Upon examination there were found to be complete paralysis of the left vocal cord and abductor paralysis of the right cord. An œsophageal bougie became arrested at a point opposite the cricoid cartilage. Gastrostomy was performed by Mr. F T. Paul in June of last year. The patient obtained marked relief from the operation and all went well until January of this year when she died. Subsequent examination showed that the growth had opened into the trachea and the right lung was the seat of a large abscess.

Mr. Damer Harrisson related two cases in which he had removed the Gasserian Ganglion for Paroxysmal Neuralgia. The first case was that of a man, 45 years of age, who for years had suffered from severe neuralgia corresponding to the distribution of the inferior dental and infra-orbital nerves. The inferior dental nerve was exposed in the bony canal and a portion of it was excised; the infra-orbital nerve was exposed and stretched. The operation was followed by complete relief of the symptoms. Some months later, however, there was a return of the neuralgia and Mr. Harrisson, after reflecting the zygoma, exposed and tore through the middle and inferior divisions of the fifth nerve. Pain was relieved for ten months but then returned again. Finally the Gasserian ganglion was excised by Rose's method. This operation was performed seven and a half years ago since then there had been no return of the neuralgia. the second case the neuralgia was confined to the distri tion of the inferior dental nerve which Mr. Harris exposed near the base of the skull and tore throu Marked temporary relief followed, but some months lat owing to a return of the neuralgia, the Gasserian gangl was excised by the same method as in the previous ca This operation was performed in 1896 and the patient been entirely free from pain ever since.

Mr. Paul, in opening a discussion on the Technique Aseptic Surgery, said that the recent changes in the tre ment of wounds did not constitute a revolution like introduction of Listerism but they were unquestionably v important and he thought that there were many advantages discussing the details of their practice. He first dealt w the preparation of the skin of the patient and said that th was a strong tendency amongst surgeons to leave this i portant matter too much to the discretion of the nurses. T hands of the surgeon were next considered. For his own p he employed the permanganate method and was well satisfi with it. Except in septic cases he did not wear rubb gloves but his assistants did. For ligatures and buri sutures he much preferred catgut, prepared according to method he described, to silk and for skin sutures he us silkworm gut. He did not hesitate to employ drainage the form of a glass tube or gauze if there was a reason to expect an accumulation of serum in the woun For dressings he preferred plain sterilised gauze a absorbent wool. In conclusion, he said that while t introduction of Listerism had been the means of savi many lives the introduction of the aseptic method ha been the means of saving much time in the more perfe healing of wounds —Sir William M. Banks said that he ha followed the whole course of antiseptic surgery from 186 when he had learnt its tenets from Professor Lister, until t day and had practised it in every phase of its developmen More and more it was resolving itself into simple bu thorough surgical cleanliness. He deprecated the lavis expenditure upon modern operating theatres and said that h found his operations done in private just as successful a those done in the most elaborately built hospital theatres He boiled everything that came in contact with the woun and for this reason preferred silk to catgut as a ligature. A to skin cleansing, if the skin was well shaved a goo scrubbing with any mild antiseptic was all that wa necessary. He had a strong opinion that aseptic surgery would soon resolve itself into boiling everything that could be boiled and shaving everything that could be shaved.—Mr. W. Thelwall Thomas thought the term aseptic when used as opposed to antiseptic unfortunate; there was no such thing as aseptic surgery in the strict sense of the term for every surgeon used chemical antiseptics for the skin. He was convinced that the deeper parts of the skin were never rendered sterile and was an ardent advocate for the wearing of rubber gloves by the surgeon and his assistants. He considered the question of aerial infection to be a negligible quantity in private practice but in hospital theatres, where septic and clean cases were operated upon, it was a matter for serious consideration, and he strongly approved of the principle of special theatres and wards for septic cases.—Mr. G. P. Newbolt compared the results of 126 consecutive cases of hernia operated upon without and with rubber gloves, the conditions otherwise being the same. In the first series 1 case in 5 suppurated. In the second series suppuration occurred in 1 case in 7.—Mr. GEORGE G. HAMILTON said that he had performed 125 major operations since May last and in only five of these had suppuration occurred.—Mr. F. C. LARKIN, Mr. DAMER HARRISSON, Dr. W. ALEXANDER, Dr. H. BRIGGS, Dr. T. B. GRIMSDALE, Mr. RUSHTON PARKER, Dr. J. E. GEMMELL, and Dr. E. T. DAVIES also took part in the discussion.

---

[2] See Twentieth Century Practice of Medicine, vol. xv., p. 331.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held on April 7th, Dr. John Campbell, the President, being in the chair.—Dr. Thomas Houston showed a case of Friedreich's Ataxia.—Dr. W. Calwell read a paper entitled "Some Observations on 193 Cases of Gastric Ulcer." He drew attention to the large number of ulcers relatively to the total number of affections of the stomach, for of 311 cases of diseases of the stomach 193 were ulcers. The probable reasons for such a preponderance were that the terms "indigestion" and "dyspepsia" were now dropped as signifying a substantive disease and were employed as a syndrome of symptoms common to many affections of the stomach. Acute and chronic catarrh, neurosis, and gastric ulcer were the three main affections in early life and of these by far the commonest before the age of 25 years was gastric ulcer. On including those cases of stomach trouble in young women with the signs and symptoms of ulcer, except hæmatemesis, there would be no difficulty in understanding the enormous rise there is during the ages from 15 to 25 years and also the large number of cases of ulcer relatively to the total number of cases of stomach trouble. A chart formed on this basis with the sexes marked independently showed that in the female no cases began *before the age of 13 years; that the line then* rose very rapidly, reaching a maximum from 17 to 19 years and fell as quickly, so that at 25 years of age there were comparatively few in the first onset; after this age cases occurred but in no great numbers. In the male practically no cases occurred before the age of 25 years (only some three were found in a total of 193); after the age of 25 years the curve was much the same as in the female. Thus there would be (1) a developmental type and (2) a post-developmental type. The former closely followed the laws of chlorosis which was confined to the female and the onset of which occurred practically between the ages of 13 and 28 years. Many cases of chronic ulcer were greatly relieved by rest in bed but with immediate return of symptoms on returning to the erect position; this was probably due to adhesions and to the kinking that took place between the first and second, or fixed, portion of the duodenum when the stomach sagged a little on the patient getting up. Sudden onset of hæmorrhage occurred in eight cases with little or no premonitory warning; in one case a small, clear-cut ulcer was discovered over a large blood-vessel. In older patients the question of œsophageal varices should be entertained as well as cirrhosis of the liver. Every girl with dyspeptic symptoms, especially if she were chlorotic, should be promptly treated as suffering from ulcer; she should rest in bed and have milk diet. True dilatation was not often, if ever, met with unless from an organic stenosis; if it were stubborn to ordinary measures nothing was so successful as a gastro-jejunostomy.—Dr. A. Dempsey spoke of the advantage of a powder of magnesia, bismuth, and soda and of, later, oxide of silver in ulcer of the stomach.—Sir William Whitla thought that the pendulum had swung too much in the direction of attributing affections of the stomach to gastric ulcer.—Professor J. A. Lindsay spoke of the value of localised tenderness on abdominal examination as a sign of gastric ulcer. He deprecated hasty surgical interference in stomach affections.—Professor J. W. Byers said that what was wanted now was to follow the lead of the continental practitioners and to get more information as to the chemistry of abnormal digestion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 31st, Mr. J. H. West Jones, the President, being in the chair.—Mr Edward Skinner showed a large Sarcomatous Tumour, weighing 14 pounds, removed post mortem from the abdomen of a man, aged 28 years, who had been under observation for five months. The tumour first showed itself in the right loin. The patient was also the subject of marked molluscum fibrosum of many years' duration.—Dr. A. J. Hall showed: 1. Two cases of Lupus Erythematosus. One was in a middle-aged married woman associated with tuberculous glands in the neck, pleural effusion, and indefinite signs of pulmonary tubercle; the eruption had improved considerably under salicin internally and previously under large doses of urea the glands had considerably diminished in size. The other was in a child, aged 12 years, with a history of recent rheumatic fever, during which the rash became much worse. 2. Lupus Vulgaris in association with Pulmonary Tuberculosis. The course of events had been tuberculous glands on the right side of the neck in childhood, secondary implication of the skin, and extension to the apex of the right lung. 3. Psoriasis in two sisters, showing marked improvement under thyroid gland alone. 4. A case of Herpetiform Dermatitis or Pemphigus. In favour of the former diagnosis was the multiformity of the eruption; against it was the entire absence of pain. 5. Hysteria in a male; there was complete loss of speech with right hemianæsthesia and slight right paresis. The patient was a single middle-aged man who had a fit in the street. On admission to hospital he was unable to utter a sound of any kind but was conscious and able to write out a full account of himself. On being asked to say "Oh" he was able to place his mouth and lips in the proper position but could not make any sound. In a few days speech gradually returned and the hemianæsthesia disappeared.—Mr. Sinclair White showed the following cases and specimens: 1. Four men whose prostates had been removed suprapubically in 1902. Their ages ranged from 61 to 72 years. All were in excellent health and had completely recovered the power to empty the bladder. 2. A series of specimens of Enlarged Prostates recently removed, including one which showed a very marked so-called middle lobe. 3. Two specimens of Cancer of the Mid-rectum recently removed by the transacral route. In both cases the rectum was slit up along its posterior surface as high as the growth and divided transversely from within outwards at least one inch below the cancer. The diseased segment was then dissected from the surrounding tissues until well clear of the upper limit of the growth when the bowel was again divided transversely. The rectal walls were then pulled down and stitched to the anal margin. He had performed Kraske's operation 18 times with four deaths. 4. One Carcinomatous and Three Myomatous Uteri removed by the abdominal route. All the patients made good recoveries. The entire uterus was removed in each case. Unless the patient was stout he preferred the abdominal to the vaginal route for removing cancerous uteri. 5. A Large Sarcomatous Growth of the Lower End of the Humerus which was removed by disarticulation at the shoulder-joint. The axillary glands were also removed as they had become much enlarged. The patient, a young female, made a rapid recovery. 6. A Partial Resection of the Stomach for a Chronic Ulcer of many years' duration situated in the upper border two inches to the left of the pylorus. The stomach walls were much thickened and indurated about the ulcer and as the patient had for some months been losing flesh rapidly it was feared that it might have become cancerous. A Murphy's button was employed to unite the duodenum to the posterior wall of the stomach. One half of the button was introduced into the stomach which was then completely closed by a double row of continuous sutures; a small opening was then made in the posterior wall of the stomach through which the shank of the button was protruded. The patient made an excellent recovery.—Mr. P. E. Barber read notes of a case of Belladonna Poisoning due to the application of a belladonna plaster to the mamma.

SOCIETY FOR THE STUDY OF INEBRIETY.—A meeting of this society was held on April 12th in the rooms of the Medical Society of London, Dr. Harry Campbell, the President, being in the chair.—Dr. Robert Jones, medical superintendent of the London County Asylum at Claybury read a paper on the Relation of Inebriety to Mental Disease. After a reference to the chemical composition of the various alcohols he described the mental effects produced by ordinary alcohol according to the quantity ingested and said that a tendency to the development of illusions of a visual character and to *delusions of a persecutory nature* was characteristic of the effects of alcohol, as was also the tendency to sudden impulsive movements. He then defined inebriety and divided the class of inebriates into two divisions, the periodic drinker and the more or less constant drinker. The victims of these two classes were of different ages, [illegible] mostly young men who, in t[illegible], were apparently rational [illegible] both to society and to their friends. There undoubtedly was in all inebriates a considerable mental deterioration, as was evidenced by the fact that over 20 per cent. of all the inebriates under treatment in retreats and reformatories were transferred during one year—1902, the last for which there were published statistics from these places—into asylums for the insane. He then gave statistics dealing with the effects of alcohol. He stated that out of the 116,000 cases of insanity at the present time detained in asylums there were probably no less than 11,000 males and 6000 females whose insanity was directly or indirectly caused through drink. He quoted the statistics of the London County Asylums for the ten years 1893–1902 inclusive and stated that during this period 35,916 persons (16,356 males and 19,560 females) had been admitted into these institutions, of whom a proportion of 21 per cent. among the men and 11 per cent. among the women were ascertained to owe their insanity to drink alone, a proportion which accounted for the insanity from this cause of 5727 persons. At Claybury Asylum there had been admitted during the period 1893–1903 inclusive 9544 persons, of whom 1664 (965 males and 699 females) owed their insanity to drink, a proportion of 22·7 per cent. among the males and 13·1 per cent. among the females. He stated that there were over 400 persons at the present time in retreats and reformatories whose detention was caused through inebriety and that this only represented a small proportion of the inebriates in the country, whose presence among the young was most injurious, both directly through their neglect and cruelty towards those for whom they were responsible and indirectly by their evil influence and example. He also referred to the loss to the community from drink through the interference with the working power of the skilled craftsman and the artisan and to the devitalising effect of alcohol on the individual and on the race. His experience of the treatment of "drink cases" in asylums had been a disappointing one as to the actual recovery which took place, for when such patients were discharged they almost invariably relapsed if they tasted alcohol at all and there were only a few who could afterwards go through life without it. The feeling conveyed by alcohol was a stimulation and among the poor it was mistaken for the feeling of nutrition and repletion after a good meal. He believed that there would be less drinking among men if women could be taught how to select food and to cook it properly.

British Gynæcological Society.—A meeting of this society was held on April 14th, Professor John W. Taylor, the President, being in the chair.—Mr. J. Furneaux Jordan read notes of a case of Hydrometra in a woman, aged 63 years, from whom 13 years previously a large ovarian cyst had been removed and who had been operated on five and a half years ago for a pyometra; there was an abscess in the scar of the old wound and the uterus was firmly adherent to the scar; a watery fluid exuded from the abscess cavity when the pus had been discharged. He also read notes and showed the specimens from a case of Double Hydrosalpinx in a woman who for ten years had been subject to attacks of abdominal inflammation.—The President remarked that these cases taken together lent some support to the idea that hydrosalpinx might be a rather late stage of pyosalpinx.—Dr. Frederick Edge showed: (1) A Myoma of the Broad Ligament; (2) a Vesical Calculus formed on a hysterectomy ligature; and (3) a Displaced Spleen simulating a broad ligament cyst and removed from the pelvis on account of torsion of the pedicle and impending gangrene.—Mr. F. Bowreman Jessett read notes of a case of Bilateral Dermoid Ovarian Cysts with torsion of the pedicle of the larger and also notes of a case of Fibroid of the Cervix which was so large as to elevate the bladder to within an inch of the umbilicus and which he had removed without any injury to the bladder.—In the discussion of the specimens Dr. H. Macnaughton-Jones insisted that hydrosalpinx might be quite independent of any pyogenic invasion.—Dr. Bedford Fenwick and Dr. Heywood Smith also spoke.—Dr. T. Arthur Helme read a paper upon the Treatment of Eclampsia by Puncture of the Spinal Canal, with notes of a case successfully treated in this way.—The President said that Dr. Helme's views as to the benefits of lumbar puncture would require to be proved by further trials; the paper was, however, not only interesting but important.—Dr. Macnaughton Jones and Dr. R. H Hodgson concurred in extolling the effects of pilocarpine and Mr. Jordan and Dr. Fenwick as to those of bleeding in arresting the convulsions of eclampsia.—Dr. Helme, in replying, pointed out that he had not attempted to criticise the action of any drugs and gave some details as to the method of puncture, the woman under chloroform being on her left side with her body so bent as to arch the back.—Dr. Macnaughton-Jones then read a paper upon the Dangers of Pessaries which was illustrated by a comprehensive exhibit of various forms of these instruments and by a series of sections of the female pelvis showing the different displacements of the womb with pessaries properly and improperly inserted. He did not by any means reject the use of supports in all cases and particularly praised that of Galabin and the figure-of-8 pessaries made, as recommended by Schultze, to suit individual cases, out of celluloid rings.—On the motion of Dr. Heywood Smith the discussion of the paper was postponed.

Hunterian Society.—A clinical meeting of this society was held on April 13th at the London Institution, the President, Dr. F. J. Smith, being in the chair.—Dr. O. K. Williamson showed a case of Morbus Cordis in a child. A loud diastolic murmur was heard beneath the second left costal cartilage and as the pulse was not collapsing in character Dr. Williamson was inclined to attribute this to pulmonary regurgitation. The great hypertrophy of the heart without sufficient valvular lesions to account for it led him to the belief that there were also pericardial adhesions. The general opinion of the meeting was that the murmur was aortic, as it was heard in the vessels of the neck.—The President showed a case of Exophthalmic Goitre in a man exhibiting the usual signs of tachycardia, tremors, proptosis, and enlarged thyroid.—Mr. H. L. Barnard exhibited a case of a Parenchymatous Goitre in a young girl. He said that if the stridor increased thyroidectomy of one lobe and the isthmus would be advisable.—Dr. W. J. M. Ettles showed a case of a Tumour in the roof of the neck on the right side and congestion of the skin and mucous membranes of the head and neck with greatly dilated venules. There had been small petechiæ on the palate. The large veins of the head and neck had not been engorged, but both retinal veins had been. The tumour was the right lobe of the thyroid probably enlarged by an adenoma, but it did not apparently exert pressure on the trachea or great veins—Dr. Ettles also showed a case of a Cervical Rib springing from the Transverse Process of the Seventh Vertebra on the Left Side in a man. The subclavian artery crossed it and simulated an aneurysm. It produced a fulness in the neck but did not give rise to any symptoms. A skiagram was shown with the case.—Mr. Barnard showed a similar case of a Cervical Rib on the Left Side but in a woman. In this case pains and weakness were complained of in the arm. No surgical interference was recommended.—Mr. Barnard also showed an extensive case of Actinomycosis of the Left Side of the Head and Neck which had been cured by the exhibition of 330 grains of potassium iodide a day and several applications of the x rays. The disease started at the angle of the jaw. It progressed rapidly until the dose of iodide reached 270 grains. About the same time the x rays were tried and the patient commenced to improve and was now practically cured. The cure was rather attributed to the potassium iodide than to the x rays. The ray fungus was found on many occasions.

Medico-Psychological Association of Great Britain and Ireland, Northern and Midland Division.—The spring meeting of this society was held on April 7th, at Scalebor Park, Burley-in Wharfedale, the new asylum erected by the West Riding County Council exclusively for the reception of private patients—Dr. J. R. Gilmour, the medical superintendent, who was in the chair, read a paper on the Value of Saline Injections in Certain Acute Cases of Mental Disease. His method was first to empty the rectum by an ordinary enema and then to inject 15 ounces of a 0·75 per cent. solution of common salt three or four times daily. Improvement in many cases followed, the mental symptoms quietening and the pulse-rate falling. The injection was rarely returned and no bad effects had been observed. The bladder had to be watched. The treatment was most useful in severe delirious cases where the strength was much reduced.—Dr. Eddison expressed the opinion that the improvement was similar to that occurring in the febrile cases in which restlessness and excitement abated when plenty of fluid was given In such cases the nervous system shared largely in the benefit produced by the much needed water.—Dr. James

Middlemass related a case of General Paralysis of the Insane where the symptoms appeared a week after a fall of three or four feet from a ladder. The patient had received compensation under the Workmen's Compensation Act, but this was withdrawn after Dr. Middlemass's opinion as to the cause of the disease was given. His opinion was based upon the following facts: the accident was comparatively slight, causing no loss of consciousness or any symptom of direct brain injury; the symptoms of general paralysis appeared in a pronounced form a week after the accident; and there was a strong presumption of a syphilitic history. The patient died and post mortem no signs of traumatism existed in the brain or skull but the state of the cerebral vessels confirmed the syphilitic theory of the cause of the disease.—Dr. Gilmour related a case where general paralysis followed a blow upon the head but in this instance post mortem, besides the signs of this disease, there was evidence of fracture of the skull and of secondary meningitis.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held in University College, Dundee, on April 8th, Dr. W. Graham Campbell, the Vice-President, being in the chair.—Professor D. MacEwan read notes of Four Abdominal Operations. The first case was one of gangrenous internal strangulated hernia. The patient, a female, aged 56 years, was admitted to the infirmary with a history of five days' vomiting and acute obstruction. The hernia was into the pericæcal pouch. The gangrenous bowel was excised and an end-to-end anastomosis was performed with Murphy's button. The patient's convalescence was uninterrupted. The second case was one of choledochotomy for gall-stones complicated with ruptured gall-bladder. The patient, who was a man, 35 years of age, had for the past ten years been subject to attacks of biliary colic. The first symptom of serious mischief was a severe attack of pain in the epigastrium accompanied by rigors and subsequently high temperature and delirium. A gall-stone was removed from the common bile duct which was then sutured. The patient's condition improved gradually without much trouble and without any fistula resulting. The third case was one of gastrectomy for cancer of the body of the stomach. The patient, who was a female, aged 43 years, was now able to take a very fair quantity of nourishment, five weeks after the operation. The fourth case was one of laparotomy for intestinal obstruction caused by an adherent appendix. The patient was a female, aged 28 years. The appendix was adherent at its *tip to the mesentery and embraced a loop of small intestine*; it was removed in the usual way and the abdomen was sutured. The patient recovered without trouble.—Mr. D. M. Greig and Professor J. A. C. Kynoch discussed the cases.—Dr. R. Cochrane Buist give some Statistical Notes on his hospital experience of Cœliotomy, Abdominal and Vaginal. There were in all 80 abdominal cases, with 16 deaths, and 43 vaginal, with five deaths. Of the *abdominal operations* 21 were upon the ovaries, with two deaths; 14 for tubal conditions, with one death; six for ectopic gestation, with one death; 14 for myoma uteri; 10 for cancer uteri; and four for displacements. 21 cœliotomies were performed for cancer, with seven deaths.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting *of this* society was held on April 14th, Mr. Thomas Richmond, the President, being in the chair.—Dr. J. A. C. Macewen showed a case of Suppurative Mastoiditis with incomplete Sinus Thrombosis upon which he had operated four and a half months before. The patient at the time of being shown to the society was in perfect health. Dr. Macewen read notes of the case from which it was seen that the patient on admission to the Elder Cottage Hospital, Govan, was in a very serious state, exhibiting as he did symptoms of pyogenic sinus thrombosis with encephalitis threatening abscess formation. Symptoms progressed rapidly during the short time that elapsed before the operation was performed, the patient being noticed to be very drowsy and difficult to rouse to answer questions for an hour or so before being operated upon. The radical mastoid operation was performed, the bone being thoroughly cleaned out by the burr; the cavity thus made having been thoroughly disinfected the dura mater covering the temporo-sphenoidal lobe was exposed. It was found to be inflamed and its vessels engorged. The membranes, however, were left intact, it being hoped that this condition might diminish with the removal of the cause. The sigmoid sinus was next exposed and it was found that though not entirely occluded in its lumen the walls of the sinus had almost completely lost their natural elasticity. Nothing further was done to the sinus. The patient made a rapid and perfect recovery. The case proved of interest to the members of the society apart from its surgical bearing, as the patient was the first upon whom a surgical operation was performed in the Elder Cottage Hospital—one of Mrs. Elder's many and noble gifts to Govan.—The case was discussed by Dr. G. H. Edington, Dr. A. Young, and the President, all of whom congratulated Dr. Macewen on the promptitude of his treatment as well as the result of it.—Dr. Macewen replied.—Dr. James Weir then read Notes on Surgical or Traumatic Rheumatism and the Use of Corrigan's Button, which were discussed by Dr. Edington, Dr. M. Dunning, Dr. J. S. McKendrick, Dr. J. C. Howie, and the President.—Dr. Weir replied.

MANCHESTER MEDICAL SOCIETY.—At a meeting of this society held on April 13th Dr. J. S. Bury, the President, gave his *presidential* address *from* the chair.—Dr. C. W. Buckley read a paper entitled "Observations on the Treatment of Neurasthenia." Objective symptoms, he said, must be the chief guide to treatment which came under five heads 1. Relief of the nervous causes; generally it was necessary to send the patient away from home and relatives for a while and preferably to a bracing climate. 2. To search for and to treat any disorders of other systems which might be accessory causes, including errors of refraction, malformations, and disorders of the mouth, nose and nasopharynx, dyspepsia and functional hepatic disorders, moveable kidney and enteroptosis, malformations and disorders of the generative organs, &c. These were all open to treatment but the influence of a neurotic heredity or up bringing could rarely be removed, nor was the increased vulnerability of the nervous system resulting from prolonged or exhausting disease open to direct attack. 3. Disorders of the vaso-motor system were common and important and should be treated by such measures as hydrotherapy, massage, and physical methods of other kinds, but electricity, though appealing to the patient's imagination, was rarely so useful; galvanism of the abdomen was often useful, especially if constipation was present. 4. Abundant nourishment must be supplied to the nervous system and must be carefully chosen so that it might be easily digestible and suited to the needs of the nervous structures. The Weir-Mitchell treatment covered all this ground but it must be rigidly carried out if it was to be successful. 5. Special symptoms, such as headache and *sleeplessness, should be treated as they arose.* Drugs he considered to be of little value.—The following specimens were shown:—1. Mr. A. Wilson: Professor Vernon-Harcourt's new Chloroform Inhaler. 2. Mr. A. H Burgess: (*a*) Sterilised Dressings in Portable Form; and (*b*) Aseptic Caps for Surgeons' use during operations. 3. Dr. R. B. Wild (in the Materia Medica Museum): Specimens of Drugs and Minerals.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 8th, Dr. R. E. Scholefield, the President, being in the chair.—Dr. A. E. Wright opened a discussion on the Treatment of Disease by Animal Extracts and Serums, with Special Reference to Practical Application. The diphtheria anti*toxic serum was*, he said, the only one that could be standardised; as to the others they might contain the poisons instead of the antidote. He quoted (1) very successful results from the use of antistaphylococcic serum in cases of boils, acne, sycosis, and paronychia; and (2) cases of lupus, tuberculous glands, tuberculous cystitis, and peritonitis benefited by the use of tuberculin. The principle of administration was to allow a sufficient time to elapse between the injections to promote the formation of protective substance. Koch's original method gave no time for the patient to respond.—The President gave his experience of 70 cases of lupus at the skin hospital at Prague which he saw when Koch's tuberculin was first used. Great improvement in nearly all the cases was the result.—Dr. F. S. Toogood said that his experience with regard to antitetanic serum *in the last ten years was that* in acute cases all the patients died, with the exception of one in whom he excised the injured part at an early stage. Chronic cases recovered without the serum which got the credit when it was used in these cases.—Mr. J. Prior Purvis instanced cases of hæmoptysis and hæmatemesis much benefited by adrenalin.—Dr. Wright, in [illegible] pains were not uncommon after and to their friends. There undoubtedly was in all inebriates a considerable mental deterioration, as was evidenced by the fact that over 20 per cent. of all the inebriates under treatment in retreats and reformatories were transferred during one year—1902, the last for which there were published statistics from these places—into asylums for the insane. He then gave statistics dealing with the effects of alcohol. He stated that out of the 116,000 cases of insanity at the present time detained in asylums there were probably no less than 11,000 males and 6000 females whose insanity was directly or indirectly caused through drink. He quoted the statistics of the London County Asylums for the ten years 1893–1902 inclusive and stated that during this period 35,916 persons (16,356 males and 19,560 females) had been admitted into these institutions, of whom a proportion of 21 per cent. among the men and 11 per cent. among the women were ascertained to owe their insanity to drink alone, a proportion which accounted for the insanity from this cause of 5727 persons. At Claybury Asylum there had been admitted during the period 1893–1903 inclusive 9544 persons, of whom 1664 (965 males and 699 females) owed their insanity to drink, a proportion of 22·7 per cent. among the males and 13·1 per cent. among the females. He stated that there were over 400 persons at the present time in retreats and reformatories whose detention was caused through inebriety and that this only represented a small proportion of the inebriates in the country, whose presence among the young was most injurious, both directly through their neglect and cruelty towards those for whom they were responsible and indirectly by their evil influence and example. He also referred to the loss to the community from drink through the interference with the working power of the skilled craftsman and the artisan and to the devitalising effect of alcohol on the individual and on the race. His experience of the treatment of "drink cases" in asylums had been a disappointing one as to the actual recovery which took place, for when such patients were discharged they almost invariably relapsed if they tasted alcohol at all and there were only a few who could afterwards go through life without it. The feeling conveyed by alcohol was a stimulation and among the poor it was mistaken for the feeling of nutrition and repletion after a good meal. He believed that there would be less drinking among men if women could be taught how to select food and to cook it properly.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on April 14th, Professor John W. Taylor, the President, being in the chair.—Mr. J. Furneaux Jordan read notes of a case of Hydrometra in a woman, aged 63 years, from whom 13 years previously a large ovarian cyst had been removed and who had been operated on five and a half years ago for a pyometra; there was an abscess in the scar of the old wound and the uterus was firmly adherent to the scar; a watery fluid exuded from the abscess cavity when the pus had been discharged. He also read notes and showed the specimens from a case of Double Hydrosalpinx in a woman who for ten years had been subject to attacks of abdominal inflammation.—The President remarked that these cases taken together lent some support to the idea that hydrosalpinx might be a rather late stage of pyosalpinx.—Dr. Frederick Edge showed: (1) A Myoma of the Broad Ligament; (2) a Vesical Calculus formed on a hysterectomy ligature; and (3) a Displaced Spleen simulating a broad ligament cyst and removed from the pelvis on account of torsion of the pedicle and impending gangrene.—Mr. F. Bowreman Jessett read notes of a case of Bilateral Dermoid Ovarian Cysts with torsion of the pedicle of the larger and also notes of a case of Fibroid of the Cervix which was so large as to elevate the bladder to within an inch of the umbilicus and which he had removed without any injury to the bladder.—In the discussion of the specimens Dr. H. Macnaughton-Jones insisted that hydrosalpinx might be quite independent of any pyogenic invasion.—Dr. Bedford Fenwick and Dr. Heywood Smith also spoke.—Dr. T. Arthur Helme read a paper upon the Treatment of Eclampsia by Puncture of the Spinal Canal, with notes of a case successfully treated in this way.—The President said that Dr. Helme's views as to the benefits of lumbar puncture would require to be proved by further trials; the paper was, however, not only interesting but important.—Dr. Macnaughton-Jones and Dr. R. H Hodgson concurred in extolling the effects of pilocarpine and Mr. Jordan and Dr. Fenwick as to those of bleeding in arresting the convulsions of eclampsia. —Dr. Helme, in replying, pointed out that he had not attempted to criticise the action of any drugs and gave some details as to the method of puncture, the woman under chloroform being on her left side with her body so bent as to arch the back.—Dr. Macnaughton-Jones then read a paper upon the Dangers of Pessaries which was illustrated by a comprehensive exhibit of various forms of these instruments and by a series of sections of the female pelvis showing the different displacements of the womb with pessaries properly and improperly inserted. He did not by any means reject the use of supports in all cases and particularly praised that of Galabin and the figure-of-8 pessaries made, as recommended by Schultze, to suit individual cases, out of celluloid rings.—On the motion of Dr. Heywood Smith the discussion of the paper was postponed.

HUNTERIAN SOCIETY.—A clinical meeting of this society was held on April 13th at the London Institution, the President, Dr. F. J. Smith, being in the chair.—Dr. O. K. Williamson showed a case of Morbus Cordis in a child. A loud diastolic murmur was heard beneath the second left costal cartilage and as the pulse was not collapsing in character Dr. Williamson was inclined to attribute this to pulmonary regurgitation. The great hypertrophy of the heart without sufficient valvular lesions to account for it led him to the belief that there were also pericardial adhesions. The general opinion of the meeting was that the murmur was aortic, as it was heard in the vessels of the neck.—The President showed a case of Exophthalmic Goitre in a man exhibiting the usual signs of tachycardia, tremors, proptosis, and enlarged thyroid.—Mr. H. L. Barnard exhibited a case of a Parenchymatous Goitre in a young girl. He said that if the stridor increased thyroidectomy of one lobe and the isthmus would be advisable.—Dr. W. J. M. Ettles showed a case of a Tumour in the roof of the neck on the right side and congestion of the skin and mucous membranes of the head and neck with greatly dilated venules. There had been small petechiæ on the palate. The large veins of the head and neck had not been engorged, but both retinal veins had been. The tumour was the right lobe of the thyroid probably enlarged by an adenoma, but it did not apparently exert pressure on the trachea or great veins—Dr. Ettles also showed a case of a Cervical Rib springing from the Transverse Process of the Seventh Vertebra on the Left Side in a man. The subclavian artery crossed it and simulated an aneurysm. It produced a fulness in the neck but did not give rise to any symptoms. A skiagram was shown with the case.—Mr. Barnard showed a similar case of a Cervical Rib on the Left Side but in a woman. In this case pains and weakness were complained of in the arm. No surgical interference was recommended.—Mr. Barnard also showed an extensive case of Actinomycosis of the Left Side of the Head and Neck which had been cured by the exhibition of 330 grains of potassium iodide a day and several applications of the x rays. The disease started at the angle of the jaw. It progressed rapidly until the dose of iodide reached 270 grains. About the same time the x rays were tried and the patient commenced to improve and was now practically cured. The cure was rather attributed to the potassium iodide than to the x rays. The ray fungus was found on many occasions.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND, NORTHERN AND MIDLAND DIVISION. —The spring meeting of this society was held on April 7th, at Scalebor Park, Burley-in-Wharfedale, the new asylum erected by the West Riding County Council exclusively for the reception of private patients.—Dr. J. R. Gilmour, the medical superintendent, who was in the chair, read a paper on the Value of Saline Injections in Certain Acute Cases of Mental Disease. His method was first to empty the rectum by an ordinary enema and then to inject 15 ounces of a 0·75 per cent. solution of common salt three or four times daily. Improvement in many cases followed, the mental symptoms quietening and the pulse-rate falling. The injection was rarely returned and no bad effects had been observed. The bladder had to be watched. The treatment was most useful in severe delirious cases where the strength was much reduced.—Dr. Eddison expressed the opinion that the improvement was similar to that occurring in the febrile cases in which restlessness and excitement abated when plenty of fluid was given. In such cases the nervous system shared largely in the benefit produced by the much needed water.—Dr. James witness is frequently placed in a most difficult position when called upon to give evidence when certain symptoms have developed in an individual who has been in a railway accident. The fact that shock alone, or shock combined with slight physical bruising, may cause serious disorders of the nervous system explains the increased proportion of nervous as compared with other affections resulting from accidents, for in accidents of general causation many persons may escape without serious bodily harm, while comparatively few are so fortunate as altogether to evade the severe mental commotion to which such disasters so frequently lead. Unfortunately, some of the cases brought before the courts are of a suspicious character, the alleged symptoms being purposely exaggerated. In the majority, however, traumatic neurasthenia has actually developed and the task of the medical examiner will be no light one. In the first place he has to assure himself that no fraud is being attempted and then he has to convince the court and the jury that functional disorders may be very serious to the individual concerned. The phenomena that may present themselves are well described by Dr. Bailey and a study of his remarks would be of great value to a medical practitioner when preparing his evidence in a case of this nature.

The articles on the medical jurisprudence of life and accident assurance by Dr. J. T. Armstrong will both repay perusal. The medical examiners attached to life assurance offices have frequently very difficult problems presented to them. Dr. Armstrong comments on many points which are likely to arise and, in addition, quotes a large number of cases which have come before the courts in relation to life assurance and this makes his observations very useful not only to the physician but also to the lawyer.

Another contribution to which we may draw attention is that on the Stigmata of Degeneration by Dr. Frederick Peterson. The question of degeneracy in its medico legal relations has come into considerable prominence in recent years owing to the researches of numerous investigators in the rich fields afforded by the asylum, the reformatory, and the prison. Dr. Peterson rightly considered the subject of sufficient importance to accord it a special chapter in this book. An excellent account is given of anatomical, physiological, and psychical stigmata, thus affording a valuable monograph on difficult and but little studied phenomena. The text-book promises to be one of the best in the English language and we look forward with interest to the publication of the second volume.

Blood Immunity and Blood Relationship: a Demonstration of Certain Blood Relationships amongst Animals by means of the Precipitin Test for Blood. By GEORGE H. F. NUTTALL, M A., [illegible] Bacteriology and [illegible] cluding original [illegible] M.A., M.B, D.P.H. Cantab., and T. S. P. STRANGEWAYS, M A, M.R.C.S. London: C J Clay and Sons; Cambridge: University Press. 1904. Pp. xii-444, royal 8vo. Price 15*s.* net.

Dr. G. H. F. Nuttall has performed a signal service to English readers by summarising and augmenting our knowledge on blood immunity and blood relationship in a volume characterised throughout by lucid and judicial treatment of a very complex subject in its practical relations to legal medicine, zoology, and physiology.

During the past five years new methods have yielded information on the chemistry of the blood hitherto impossible of attainment. Methods of investigation originally devised by Bordet and Ehrlich solely because of the theoretical bearing which they promised to have upon some disputed points in the study of immunity have ultimately developed so as to become of eminent practical value to the zoologist, the physiologist, and the medico-legal expert. Bacteriology, and more particularly its specialised following out in relation to the problems of immunity, has, not without justification at times, been subject to much adverse criticism through some of its devotees advancing as facts what others, not so enthusiastic, have rightly held to be mere explanatory hypotheses. But in the particular development of immunity which forms the subject of Dr. Nuttall's treatise medical men have turned the tables on the biologist, the physicist, and the chemist, the results of whose more exact methods have been called in—occasionally rather empirically—to bolster up this or that hypothesis of immunity. The methods so ably expounded, practised, and perfected by Dr. Nuttall have in the hands of purely medical men yielded exact information and assistance of a kind which the physicist, the chemist, and the biologist have been unable to afford to the efforts directed to solve some of the problems inseparably bound up with those albuminous bodies which lie at the basis of life. These methods have demonstrated differences in the albumins which were hitherto unsuspected and incapable of being made evident by the best methods at the disposal of the chemist and the physicist.

The book opens with a clear and succinct account of facts relating to antibodies in general other than the "precipitins." In this *résumé* the facts are naturally regarded in the light of Ehrlich's side-chain theory but the author does not digress into hypothetical discussions. As is well known, Ehrlich, like Metchnikoff and Bouchard before him, seeks to explain the phenomena of immunity as manifestations of modified processes of assimilation. Ehrlich regards his explanation as a purely chemical one in which the antibodies are formed because the cell endeavours to assimilate bodies which it cannot distinguish from true foodstuffs. The cell is compared to a benzene nucleus and, like the latter, is assumed to enter into chemical relations by means of "side chains." This view has found apparent support in the production of antibodies to the albumins which are foodstuffs per os. This is undoubtedly a most ingenious conception but a moment's reflection leads us to doubt if the antibodies are formed solely because the bodies leading to their production are, or simulate, foodstuffs, for the whole series of the carbohydrates which are foodstuffs of equal importance with the albumins, and may therefore legitimately be supposed to unite with side-chains, are incapable of leading to the production of antibodies. Ehrlich's views would be capable of much more ready acceptance if antibodies existed to the carbohydrates. Since they do not do so we are inclined to ask what is the rôle played by the chemical constitutions of the series of substances which lead to the production of antibodies directed against themselves.

We have only one criticism to offer concerning Dr. Nuttall's book and it is in regard to the chapter in explanation of immunity in general. Our criticism is that if the literary and polemical contributions to the discussion of Ehrlich's side-chain theory by Baumgarten, Gruber, Emmerich, and Loew were worthy of mention surely the serious and valuable experimental investigations of Bordet, Buchner, Arrhenius and Madsen, Muir, and many of the pupils of Metchnikoff and Behring were also worthy of mention. For it is perhaps not without significance that among the large following of Ehrlich the names of those whose authority as investigators and pioneers in the fields of immunity is as great as his are not to be found. No doubt Dr. Nuttall wished to avoid too lengthy a discussion. We cannot, however, but regret that he has not taken up a task which he is eminently fitted to perform in an impartial manner.

There is no subject in medical literature so burdened as is immunity with laboratory jargon which means anything or nothing according as the reader is an adherent or an opponent of some particular explanatory hypothesis. Throughout Dr. Nuttall carefully distinguishes facts from explanations and with considerable tact limits his use of technical phrases to terms aptly expressive of what is meant; this of itself is a most valuable feature in such a volume.

It is now known that antibodies are produced for various immunising substances other than the toxins and their allies. In the careful following out of the consequences of immunising with different albuminous bodies it has been ascertained, to put it generally, that each albuminous body—there are, of course, limitations—may lead to the production of an antibody directed against itself. Extensive study has shown that the specificity of these reactions is so rigid that the albuminous constituents of the flesh and blood of one species of animal can by their agency be distinguished from those of another. If the serum or flesh-albumins of one animal be used to immunise another of alien species, the serum of the latter acquires a "precipitin" or precipitating substance, by virtue of which a "precipitum" falls out when the immune serum is brought into contact with the serum used to produce the immunity. The reaction is one obvious to the naked eye and requires no subsequent following out in animal experiment as in the case of toxin and antitoxin, which react with one another in the test-tube without visible accompaniment. This is the broad principle. In its actual carrying out there are many pitfalls which Dr. Nuttall is careful to point out and to show how to avoid. The book is essentially an exposition of the practical bearings of the above facts and of the methods suited to the satisfactory application of the precipitin test in medico-legal, zoological, and physiological investigations. As such it is both successful and interesting.

From the great mass of experiments recorded by Dr. Nuttall and by Mr. Strangeways and Dr. Graham-Smith, who have worked at his instigation at the zoological application of the method, it is with truth stated that "the results speak for themselves and show beyond question that much may be accomplished by the use of the precipitin tests in the study of blood relationships," a study which it has hitherto only been possible to take up from the purely morphological aspect. The zoological application of the "precipitin tests" is based upon the fact that there are gradations in the degree of the specificity of the reactions. This tends to become less marked the more nearly the species of animal are related to one another so that positive reactions are obtained with the serum of animals nearly allied to each other. The "precipitin reactions" are also of sufficient delicacy and constancy to find what is probably their chief practical importance in their application to medico-legal investigations. Their medico-legal value has survived scrutiny in a way which indicates very strongly how potent may be their influence in condemning a murderer to the gallows or in removing suspicion from the innocent. The chapter devoted to the results of the applications which have up to now been made in criminal cases reads like a veritable romance. The test has proved itself useful for the identification of blood, blood stains, meats, bones, and the detection of adulteration of meat and food generally by demonstrating the presence of albuminous bodies which should be absent. It is truly a matter of great moment that a prisoner who may claim that a blood stain has been caused by bullock's or rabbit's blood can have his claim substantiated by a scientific proof of his veracity, and, on occasion, the demonstration that a stain has been produced by human blood may be of equal moment. In this connexion the "precipitin test" must prove a most valuable adjunct to the procedures upon which confidence has hitherto of necessity been placed.

The author points out that this test has already been officially recognised in Germany, Austria, Roumania, and Egypt for medico-legal purposes. In Germany those scientific institutes where the test may be performed in a satisfactory manner are stated in the regulations pertaining to it. Dr. Nuttall is at great pains to point out the difficulties which attach to its proper carrying out and to the necessity for experience in passing a judgment on the results. We fully agree with Dr. Nuttall and while recognising the claims which he puts forward for the "precipitin test" we are most emphatically of the opinion that its carrying out for medico-legal purposes cannot be lightly intrusted to any dabbler in immunity but only to the very few who by experience are aware of the many pitfalls that are almost certain to obscure the issue in less experienced hands.

From the public importance of the "precipitin test" we commend the book in the first instance to the serious consideration of those engaged in medico-legal practice and also to biologists and all medical men as an eminently successful exposition of a very difficult, but very valuable and painstaking, research into the practical and public value of an outcome of the study of immunity. The book is accompanied by an excellent index and by valuable cross references throughout. Finally, we congratulate Dr. Nuttall on the most comprehensive treatise which has appeared on the "precipitins" in English or in any other language.

Diseases of the Eye. By L. Webster Fox, A.M., M.D., Professor of Ophthalmology in the Medico-Chirurgical College of Philadelphia, Pennsylvania. With five Coloured Plates and 296 Illustrations in the text. London: Sidney Appleton. 1904. 8vo, pp. 584. Price 18s net.

The demand for treatises and text-books on the eye must be very great. Is it, as we may piously hope, that there is a genuine desire on the part of students to make themselves acquainted with the pathology and treatment of the diseases of this little organ where so much is patent that in other regions is concealed from view? Is it that its study attracts the anatomist, the physiologist, the pathologist, the surgeon, the physician, and even the mathematician? Or is it due—we blush to ask the question—to the inclusion of ophthalmology in examinations in many different branches of medicine, to the establishment of professorships in universities, and to the great increase in the number of hospitals? Time was, when with Middlemore, or Lawrence, or Mackenzie, the young practitioner could boldly diagnose and treat any case of disease of the eye that might present itself to him. Now, with books around him that lie thick as the leaves in Vallombrosa he must spend many months in mastering the rudiments of ophthalmology; and after all, knowing how rapid is the development of this branch of medicine, when an ophthalmoscopic or refraction case does present itself in his practice, if the patient is one whom he is unwilling to run the risk of losing by an error in diagnosis, he probably thinks it expedient to send him with a note to the specialist in the nearest town.

The author states in the preface that the work is based on an extended experience and that the ordinary and well-known facts of ophthalmology are supplemented by his own views of pathology and methods of treatment. A careful perusal of the treatise leads us to endorse both of these statements. Dr. Fox is evidently familiar with the diseases of the eye, has formed his own opinions, and does not fear to express them. The subjects of refraction and of the motor disturbances of the eye to which American surgeons have paid so much attention are relegated to the end of the volume but the various diseases are discussed in topographical order, commencing with the eyelids and proceeding through the conjunctiva, cornea, sclera, and other tissues to the retina, optic nerve, and orbit. Good cases with drawings show the excellent results obtained from the employment of the x rays in the treatment of infectious ulceration of the eyelids and also in cases of epithelioma and rodent ulcer and in sarcoma of the orbit. It is evident that this mode of treatment of serious forms of disease is gaining ground and unexpected results may be obtained hereafter in cases at present regarded as hopeless.

The treatment of ptosis seems to have attracted the attention of many surgeons and much ingenuity has been expended in devising operations for its relief. Thus Dr. Fox has noted, and briefly described, those of Birnbacher, Everbusch, Ferguson, Gillet, de Grandmont, Gruening, Motais, Mules, Pagenstecher, Panas, Allport, Tansley, Wilder, Wolf, Jessop, Hess, and Komoto, and finally gives his own which consists in drawing down the affected lid until its edge is directly opposite to that of the lower lid and the extent of the redundant fold of skin is ascertained; an incision is then made across the full width of the lid a few lines above its ciliary margin and parallel with it. A second incision is made parallel to this and at a sufficient distance from it to inclose the excess of tissue between them. The flap is then dissected off by scissors and the skin above the upper incision is freed from its underlying attachments. The margins of the wound are approximated and united by interrupted sutures near the free margin of the lid. No scar is said to follow and ectropion is avoided by the undermining of the skin of the lid before suturing it to the ciliary margin. Dr. Fox states that the ultimate results are good and permanent. Nearly as many methods for entropion and ectropion are described.

The author rightly states that in the whole range of ophthalmic surgery nothing gives more trouble and annoyance to the surgeon and more discomfort to the patient than the various forms of obstructed duct. He has himself devised a good form of gold cannula which is adapted for permanent wear. He prefers the use of large-sized probes after the canaliculus has been divided and their retention for the comparatively short period of 15 or 20 minutes. Speaking of onyx, Dr. Fox mentions a remedy, we believe not generally known in this country—cassaripe—which is the inspissated juice of the cassava, which, we presume, is the Jatropha manihot. It is said to be highly antiseptic and at the same time free from irritating qualities. It may be freely rubbed into the conjunctival folds two or more times daily. It is serviceable not only in onyx but in corneal ulcers and infectious inflammations such as purulent ophthalmia. Dr. Fox has an instructive chapter on the best mode of dealing with cases of conical cornea. American patients decline operative procedures such as the application of the actual cautery and the formation of an artificial pupil, but he has obtained good results by placing before the eye black discs with openings of various form (of which illustrations are given) and the use of appropriate glasses to correct errors of refraction.

In the account of the operation for the extraction of cataract the question of the performance of an iridectomy is left open. The author states (which is not, we believe, in accordance with custom in this country) that the pupil should always be dilated one hour before the operation is performed. Great pains are taken to remove all particles of the cortex, the eye is washed with sterile boric acid solution, and if iridectomy has not been performed the pupil is contracted after extraction of the lens with one drop of eserine. Sufficient stress is not laid on the danger attending operations for secondary cataract. Many eyes have been lost by this proceeding. The author airily speaks of incising the cornea with a broad needle and entering the capsule in the vertical direction. De Wecker's scissors are then to be introduced through the corneal opening and the blades separated, one blade passing behind the capsule, and the other horizontally in front. "With one snip the capsule is cut in two." This is all very well but what is to be done when the capsule is tough and the cut made by the scissors does not gape? or if in penetrating the capsule the iris gives signs of being dangerously dragged upon. Dr. Fox has met with no less than five cases of black cataract. He gives an interesting account of the mode of utilising the Roentgen rays in detecting and localising foreign bodies in the eye and describes a very simple and apparently very efficacious instrument which acts as a localiser. In the skiagram showing a bullet located in the skull below and behind the orbit owing to some imperfection in the printing the bullet in our copy appears to be of the size of a six-pound cannon ball.

As a rule the illustrations are sufficiently characteristic of the diseases which they are intended to represent. Exception must, however, be made in the drawing representing Hutchinson's teeth. Corneal opacities, again, are not very favourable subjects for illustration, especially when the cornea is represented by a black circle. The appearances presented are here materially modified by the impression in printing. Again, we doubt whether the illustration on p. 183 would be recognised even by an expert as representing coloboma of the iris. On the other hand, there is a good and original diagram showing the nerve centres that are in relation with the movements of the pupils.

There is a glossary which requires revision. Thus, "abatio retinæ" should be "ablatio retinæ"; "illaquestion" should read "illaqueation"; "ireankistron" should read "iridankistron"; "ceratitis," "ceratocele," and "ceratome" are all better spelled with an initial k, all being derived from κέρας, horn. Should not "pacheablephara" be "pachyblepharon"? In what treatise on the eye that the student or the practitioner is likely to read would he meet with such terms as "marmarygæ," "pladarotes," and "rhytidosis"? The space given to these antiquated terms might have been better occupied by such words as "hemianopsia," "dyslexia," "polycoria," and many others that are in common use. These are, however, but minor blemishes in what is otherwise a well-arranged treatise enriched by many original observations, containing a clear but comprehensive account of the present state of ophthalmology, and in all respects worthy of careful study.

The Medical Annual: a Year-book of Treatment and Practitioner's Index. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1904. Pp 852 Price 7*s.* 6*d.* net. Stereoscope 2*s.*

WE have pleasure in welcoming this, the twenty-second, issue of the "Medical Annual." In these days when so much work is being done by members of our profession it is difficult for practitioners to keep themselves abreast with the most recent views of medical subjects without the aid of such works as the one under review. The various departments of medicine are reviewed as in former editions. There is such a wealth of material in the volume that we can only comment on a few of the subjects discussed. In the summary on therapeusis attention is properly directed to helmitol as being a more powerful urinary antiseptic than urotropin; a case of bacteriuria is cited that had resisted treatment for years but was finally cured by this drug in three weeks. The most recent facts on serum therapy are well summarised, whilst with regard to the therapeutic action of the *x* rays in lupus, rodent ulcer, and epithelioma the reader will find a good account of this agent up to date. The same applies to the article on radium. With regard to the infectious fevers, some doubt appears to exist as to the efficacy of adrenalin chloride in intestinal hæmorrhage in enteric fever, the good results that have been obtained by some observers not having resulted invariably. The same remark applies to the treatment of small-pox as regards the keeping of a patient in red light. In the section on pulmonary affections we find that the pathology of asthma receives satisfactory attention. The questions in connexion with pleuritic effusion are considered, whilst the difference of opinion as regards the relationship between human and bovine tuberculosis shows that the matter is not yet definitely settled one way or another. With regard to nervous diseases, some advance has been made in the treatment of epileptic patients, more especially as to their dietetic treatment The diagnostic results of lumbar puncture are seen to be of considerable value and attention is drawn to the value of Lott's hyoscine treatment of the morphia habit.

As regards the treatment of tetanus by antitetanic serum, where the latter is not available Baccelli's method of injection of 2 or 3 per cent. of carbolic acid is to be borne in mind, as good results have been recorded by the Italian physicians. The number of analgesic drugs is shown still to be increasing and in connexion with them we see mentioned the immediate relief of pain claimed by Cordier of Lyons by means of the subcutaneous injection of atmospheric air in sciatica. Out of 25 cases Cordier claims to have cured 23, injections being given once a week for four or five weeks. Other methods of treating this troublesome affection are cited. In the domain of tropical diseases a great advance in the pathology of sleeping sickness has been made owing to the discovery of the relation of trypanosomata to the disease. In connexion with plague we have learnt the heroic dose of carbolic acid that can be tolerated by the human subject. The reader will also find much interesting matter relating to beri-beri, craw-craw, lathyrism, leprosy, malaria, and yellow fever.

The subject of gout has received much attention and here Dr. F. S. Toogood's paper is worthy of consideration. The bacteriology of arthritis and rheumatism would appear not to have been advanced appreciably during the last 12 months. With respect to diseases of the kidneys, a novel departure in the treatment of these affections is seen in the surgical interference recommended both for acute and chronic Bright's disease. In the former it is apparently advocated only when one kidney is affected. In diabetes the relationship of the pancreas to this disease has had further light thrown upon it, whilst non-diabetic glycosuria has been more clearly elucidated. We have no further space in which to notice the good work that has been done in children's diseases, affections of the eye, the nose, and the throat, and other departments of medicine, but mention in conclusion must be made of a new feature in the "Medical Annual" of this year—viz., the provision of a stereoscope for viewing the admirable plates contained in it. This constitutes one of its most valuable features.

Clinical Examination of the Urine and Urinary Diagnosis. By J. BERGEN OGDEN, M.D., late Instructor in Chemistry, Harvard University Medical School; Assistant in Clinical Pathology, Boston City Hospital. Illustrated. Second edition. Thoroughly revised. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 418. Price 12*s.* 6*d.*

THE object of this work is to present in as concise a manner as possible the chemistry of the urine and its relationship to physiological processes; the most approved methods of examining the urine for clinical purposes; and the diagnosis of diseases and disturbances of the kidneys and the urinary passages. That Dr. Ogden has succeeded in his endeavours is shown by the fact that a second edition has been found necessary. The first part of the volume describes the constituents of the urine, normal and abnormal, and the processes adopted in chemical and microscopical examinations. In the present edition important changes and additions have been made in the chapters devoted to those subjects in order to make the text complete. The most modern methods for determining urea, uric acid, and the "total nitrogen" have been included. Some remarks have been introduced on the presence of β-oxybutyric acid in the urine and its clinical significance. This substance is met with in large amounts in the urine of patients suffering from the severe forms of diabetes mellitus and in small amounts in scurvy, scarlet fever, and measles. Its occurrence in diabetes would seem to be of serious import as it is probably the cause of the acid intoxication which usually precedes and accompanies diabetic coma. Its isolation is rather difficult. The determination of the freezing point of urine (urinary cryoscopy) which was first studied and used by Bouchard in 1870 and which has received considerable attention from various observers during the past two years is briefly alluded to. The process is a complicated one. The ratio of the freezing point of the urine to the percentage of sodium chloride sometimes furnishes information of some value in the diagnosis of heart disease and chronic nephritis. As Dr. Ogden points out, however, the subject requires further investigation before much practical value can be ascribed to it.

Only minor changes have been made in Part II. which deals with the various morbid conditions which may affect the kidney.

LIBRARY TABLE.

New Poems. By RONALD CAMPBELL MACFIE. London: John Lane. Pp. 134. Price 5*s.* net.—Mr. Macfie is a true poet—that is to say, he has the faculty of what Ruskin called "imagination penetrative." He sings about what for want of a better name we vaguely call natural forces and we cannot call to mind any poet since the days of Lucretius who has done so. Erasmus Darwin, of course, wrote "scientific poetry," but it was neither poetical nor scientific any more than was The Loves of the Triangles, by which Darwin's effusion is now mainly remembered. Mr. Macfie, however, is impressed—as who is not?—by the enormous advances recently made in our knowledge of the nature of atoms and the hypothetical ether and writes very finely in such a passage as this:—

"Beyond the blue, beyond the red
The waves of ether fast and slow,
Against our eyelids vainly beat
Vainly atween our eyelids flow;
And yet to the clairvoyant dead
What various colours they may show!

* * * * * *

Beyond the billows of the air
That brings the sounds of every day,
Ten thousand tiny ripples dance
Ten thousand little currents play
Whereby the dead become aware
What words the silent roses say,

And learn the secrets of a star,
And catch the breathing of the spring
And hear above the scythe of death
The disembodied spirits sing
And God's eternal heart afar,
Like a loud ocean thundering."

There is a striking passage also in the same vein of thought in the poem "To the Queen of England." Mr. Macfie, however, can play deftly in other keys; witness his charming little songs "A Keepsake," "Youth and Age," and "A Rosary." Altogether we think that Mr. Macfie is distinctly in the first rank among our younger singers.

Proposed Sterilisation of Certain Mental and Physical Degenerates. By R. R. RENTOUL, M.D. R.U.I. London: The Walter Scott Publishing Co., Limited. Pp. 26. Price 1*s.* net.—So far as anything explicit can be gleaned from Dr. Rentoul's book two main propositions appear to be advanced in it. One is that it is not advisable to interfere with "Nature's method—that of suicide" for "the care of lunatics," and the other that sufferers from certain diseases "should, if they wish to marry, be sterilised." As to the first of these Dr. Rentoul seems to lack the courage of his convictions, for on p. 11 he says that "no thinking person can advocate a policy of murder. These poor degenerates have a perfect right to live." The second is based upon assumptions relating to heredity which are, to say the least, unproved. No other way of salvation is open because "in the Ten Commandments it has been finally enacted that the faults or sins of parents shall be visited upon the children" and "no science—no human effort—can get behind this." Perhaps, however, this loosely-written pamphlet may not contain the last word on the social problem.

JOURNALS AND MAGAZINES.

The Practitioner.—The April number of this journal deals with a variety of subjects. An article by Dr. R Salusbury Trevor deals with the functions and the pathology of the pancreas—a branch of medical inquiry which becomes of increasing practical importance with the progressive explorations of the abdominal surgeon of to-day. Dr. H. Campbell Thomson reviews recent literature bearing upon cerebral and mental diseases in relation to general medicine, and Mr. H. S. Clogg bases upon 25 cases some pertinent remarks concerning carcinoma of the colon. Not everyone will agree with the details of Dr. P. R. Cooper's recommendations in a plea for aseptic midwifery. His article, however, is a "counsel of perfection," and its principles at least are unexceptionable. Dr. Mott contributes the first of his lectures on Progressive Muscular Atrophy.

Medical Electrology and Radiology—The March and April numbers of this journal may be conveniently mentioned together, several articles being in a serial form. Dr. W. S. Hedley, the editor, in a review of the progress made during 1903 deals with the therapeutic applications of direct heat rays from a luminous source, the light of arc lamps, and light of various colours; he then discusses the conditions determining the permeability of animal tissues to the Roentgen rays, the therapeutic effects of the rays, and the measurement of their quantity and quality. Articles of which instalments appear are: Treatment of Affections of the Gastro-Intestinal Tract by Electrical Methods, by Dr. George A. Herschell; Methods of Application of High-Frequency Currents, by Mr. Clarence A. J. Wright; and Lectures to Medical Practitioners on Physics applied to Medicine, by Sir Oliver Lodge. American news and reports of the meetings of the British Electro-therapeutic Society are given as usual. In the April number there is an account of a fatal shock received in a bath from the water-pipes conveying currents which had escaped from a tramway service.

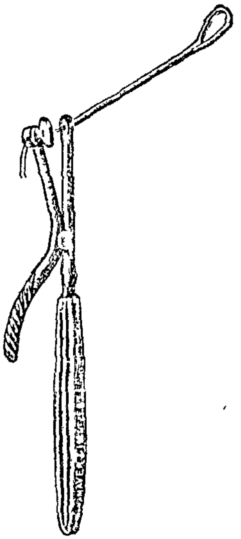
Climate.—In the April number of this journal Dr. C. F. Harford, the editor, writes on Sleeping Sickness and the Trypanosoma. Other articles deal with the Anti-malarial Measures in Ismailia, the Examinations in Tropical Medicine and Hygiene at the University of Cambridge, the Treatment of Ulcers, and various medical and dietetic hints for missionaries and explorers

South African Medical Record.—In addition to a variety of original communications the March number contains reports of two meetings of the Cape Colony Medical Council. An editorial article is devoted to the mutual relations of hospitals and the medical profession; in the course of it there is a judiciously-worded protest "against the tendency so prevalent in South Africa to divorce hospital from general practice by putting the larger hospitals under the control of salaried men who are retained for that work alone and keeping the general practitioner from active connexion with them."

COLONIAL NURSING ASSOCIATION.—Her Royal Highness Princess Henty of Battenberg has consented to be present at the annual meeting of the Colonial Nursing Association to be held at Sunderland House, Curzon-street, by kind permission of the Duchess of Marlborough, on Wednesday, June 8th. Lord Grey will preside.

New Inventions.

POST-TURBINAL SNARE.



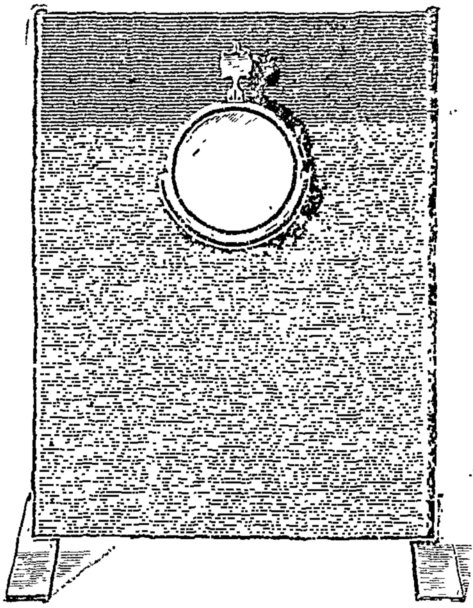
THIS snare has been designed to facilitate the snaring of the posterior ends of the inferior turbinals without a general anæsthetic and without the insertion of a finger into the post-nasal space. If used with a finger in the post-nasal space it is more quickly adjusted and more easily held in position than an unsupported wire loop. The wire loop runs in the rigid grooved loop, the groove being continuous with the barrel of the snare. The grooved loop is bent upwards at a slight angle to the barrel and the same instrument can be used for the right and left posterior ends manipulated by the right and left hands respectively. There is a stop in the barrel to prevent the severed posterior end dropping off the wire. The wire is readily replaced in the groove if the former be a medium or a fine one. The rigid grooved loop carrying the wire enables the posterior end of the turbinal to be felt for where this is not in view from the anterior nares and takes the place of the finger in the post-nasal space by insuring its encirclement by the wire and retention of it in position during the process of tightening the snare. The snare has been made for me by Messrs. Mayer and Meltzer, 71, Great Portland-street, London, W.

MACKAY MACDONALD, M.B., B.C. Cantab.,
Senior Clinical Assistant to the Throat Department, King's College Hospital.
Harley street, W.

A NEW COLOUR TEST APPLIANCE.

THE following is a description of a new appliance for testing the colour vision which, I venture to suggest, will be found useful for the examination of candidates for the various public services. It consists of a dead-black metal screen 14 centimetres in height by nine centimetres in width, supported on two metal cross-bars. Just above the centre of the screen there is an oval aperture about three centimetres in diameter; around the lower half of the aperture is fixed a double groove, similar to that in a trial spectacle frame, for the purpose of carrying the coloured discs and diaphragms employed in the test. In addition to the above there are four coloured mounted glass discs, blue, red, green, and yellow respectively, one ground-glass disc, one smoke-glass disc, and three black vulcanite discs having central apertures, the diameters of which have been designed approximately to test the acuteness of the colour vision at varying distances of 100, 300, and 500 yards. There is also a card upon which appear four squares coloured to correspond with the four coloured discs

The method of using the test is as follows. The screen is placed upon a convenient table with a light behind it, the candidate to be examined being seated upon a chair about four metres distant. In the candidate's hand is placed the card with the coloured squares. One of the coloured discs is then inserted in the groove in front of the aperture in the screen and the candidate is first asked to name the colour and next to point to it on the card. The remaining colours are similarly tested. Lastly the acuteness of the colour vision is further inquired into by inserting the vulcanite diaphragms in front of the coloured discs. The ground-glass and smoke-glass discs are for the purpose of delineating "misty" and "foggy" atmospheric conditions.

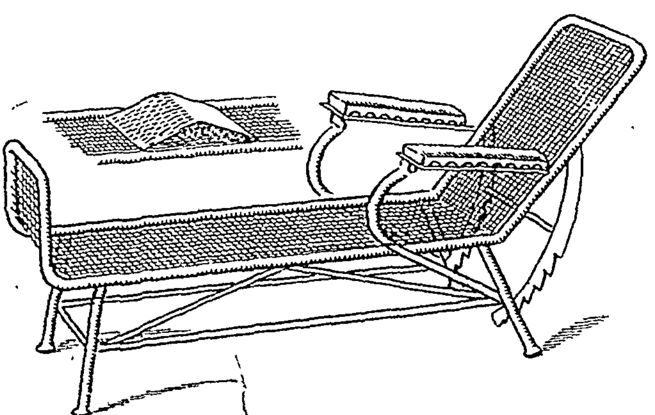


The appliance is supplied in a neat mahogany box and can be obtained from the manufacturer, Mr. F. Davidson, 140, Great Portland-street, London, W., to whom I am much indebted for the care with which he has carried out the design. The cost is very moderate.

PERCY DUNN, F.R.C.S. Eng.,
Ophthalmic Surgeon to the West London Hospital; Lecturer on Ophthalmology at the West London Post-Graduate College.
Wimpole-street, W.

A NEW SANATORIUM CHAIR.

THE accompanying illustration shows a "sanatorium chair" which I have designed and modified after that as used at Belitz, Berlin. During my visit last year to some of the oldest and newest, both public and private, sanatoriums in Germany, the Black Forest, and Switzerland, the one thing I looked out for was a "chaise longue" which might be adapted to any patient. There are here at Bowdon 50 chairs in continual use; these are of cane, firmly made, strengthened by iron supports, but these are unsatisfactory from many points of view. The seats or horizontal portions of chairs are all of the same length and curve, so that tall as well as short patients find them uncomfortable and inconvenient. Mattresses are not being used here, their place being taken by a plentiful supply of rugs. Those who have control of a sanatorium for consumptives know how costly these chairs may be, as they are being continually repaired, the seats and back supports "sag," give way, and the cane unravels; some are temporarily mended or patched with thick twine, pieces of canvas, or carpet so that they look anything but neat and clean. In the sanatoriums which I visited mattresses and pillows for the chairs were used, most had cane chairs, the exceptions being in the new sanatoriums at Davos (German), Harlaching (Munich), Belzig, and Belitz (Berlin) where iron chairs were employed. The medical directors of the various sanatoriums told me that they found the cane chairs did not give satisfaction owing to constant repairs, renewal, and short "life-history." The points aimed at in my design are neatness, simplicity, cleanliness, durability, and adaptability to suit a patient of any height. The framework is of iron, fitted with a wire mattress (the back and seat portions being in one piece); the arms are covered with leather, the back support being adjustable to any angle. I suggest that no hair or "flock" mattress should be used but that instead thick felt material similar to that as used for stage purposes by acrobats and others. Such a "mattress" would be clean, easily rolled up and carried indoors at night, and, above all, sterilisable; on top of this would be placed the wedge-shaped pillow or knee-support depicted in the illustration; this may also be of wire or cane and should be of the same (inside) width as the frame of the chair, easily slid along the mattress under the knees of the patient, and in this way making the chair adaptable to persons of any height. The chair may be had of Mr. Edgar Samuel, Port Talbot, South Wales.



Manchester Sanatorium, Bowdon, Cheshire. D. LLOYD SMITH.

A MEDICAL BAG.

I HAVE lately had made for me a bag which I think should prove useful to a large number of medical men. It is of an ordinary "kit-bag" pattern, measuring 16 × 8 × 8 inches. It contains two pockets and the usual arrangement for bottles, loops for a case of catheters, and a steriliser measuring 14 × 3½ × 2½ inches inside, which latter will thus take a pair of midwifery forceps or the necessary instruments for most operations, including silver catheters. The lid can be used as a tray during operations and supplies a receptacle never obtainable in private houses, whereas bowls and other necessaries of this description are always at hand. It has been made by Messrs. Bailey of 38, Oxford-street, London, W., who have also put up for me some packets of sterilised gauze already cut up which can be either used as swabs or dressings. Each packet contains a dozen pieces and its contents can be turned out into a bowl of lotion without any direct handling. One has ready at once with these dressings and steriliser all the means for conducting an aseptic operation in a convenient and portable form. Towels which have been boiled can almost always be produced whilst the bandages and wool can be easily kept sufficiently clean. As I have had considerable difficulty in getting what I wanted and as it seems to me of such general utility I thought it might be of some service to indicate where such equipment can be obtained. Convenient methods of sterilising midwifery forceps are seldom, if ever, forthcoming and the stock pattern sterilisers are either too small or too cumbersome, whilst already cut up and sterile dressings obviate the expenditure of a large amount of time and trouble. The bag has sufficient capacity to contain the steriliser and all the instruments and dressings most usually needed, whilst the whole outfit is just as portable as the ordinary general practitioner's bag and, in fact, also serves this purpose. ALEX. R. TWEEDIE, F.R.C.S. Eng.

Market Harborough.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on April 13th at 11, Chandos-street, Mr. Christopher Heath, the President, being in the chair. One new member was elected and the deaths of six members were reported. Two widows had become ineligible for further grants. Fresh applications for grants were read from four widows and assistance was given to three, the fourth not being eligible under the by-laws. 54 widows, 14 children, and four orphans on the Copeland Fund applied for a renewal of their grants and £1319 were voted for distribution at the next court. A legacy of £1000 from the late Mrs. Du Pasquier was announced. The following gentlemen were nominated for election at the annual general meeting to fill the vacancies in the court of directors: Mr. E. C. G. Snell, Mr. W. T. N. Bell, Dr. C. Godson, Mr. E. H. May, Dr. W. C. James, Mr. A. W. *Green*, and Dr. S. West. The expenses of the quarter were £57 3*s*. 6*d*. It was decided to hold the annual general meeting at 5 P.M. on Wednesday, May 18th.

THE LANCET.

LONDON: SATURDAY, APRIL 23, 1904.

The Isolation of Small-pox in Germany.

FOR many years past it has been alleged by the opponents of vaccination that the immunity from small-pox which is enjoyed by the inhabitants of the Fatherland is ascribable not to the system of compulsory vaccination and revaccination which obtains in the German Empire but rather to the hospital isolation which it is alleged is practised therein. Mr. WALTER LONG, with his customary far-sightedness and independence, determined recently to have the matter investigated by a member of his own medical staff, and consequently Dr. R. BRUCE LOW, the second assistant medical officer in the medical department, was directed to proceed to Germany in order to make the necessary investigations and to report to the President thereon. Dr. LOW visited ten of the principal towns in Germany—i.e., Berlin, Cologne, Frankfort-on-Main, Wiesbaden, Mayence, Munich, Nuremberg, Dresden, Leipsic, and Stuttgart—and at each place he made detailed inquiries as to the method of dealing with cases of small-pox and as to the isolation accommodation provided for such cases.

In the very interesting and instructive report which has just been published[1] Dr. LOW furnishes maps showing in the case of almost every town visited the precise position of the small-pox pavilion, if such it can be called, and of its relation to the surrounding buildings. The reader of the report is at once struck by the fact that in nearly every town the pavilion used for the isolation of small-pox is part of the general hospital, and further that such pavilion is in many instances not separated from the pavilion used for the isolation of cases of other infectious diseases; indeed, we are told in the letterpress that in several places no separate provision whatever is made but that when a case of small-pox occurs the patients from one of the pavilions are removed and the small-pox case or cases isolated therein. It appears, moreover, that in most instances the pavilion used for small-pox cases is supplied with food from the general kitchen and that the soiled linen of the patients is sent after disinfection to the general laundry. It is quite clear, therefore, that the immunity of Germany from small-pox is in no sense due to the arrangements for isolating cases of this disease, seeing that there is practically no special provision whatever; in fact, the Germans seem to treat the whole question of the isolation of small-pox in a manner which we in this country would be inclined to regard as very unsatisfactory and eminently casual. But this notwithstanding it appears to suffice. In Berlin, with a population of just under 2,000,000, there are 12 beds reserved for small-pox. In Cologne, with a population of 399,126, no beds are reserved. At Frankfort-on-Main a similar remark applies. At Mayence, the only town visited in which separate accommodation exists, only one case of suspected small-pox has been isolated there and the building is now used for patients convalescent from non-infectious diseases. At Munich there is a pavilion for 14 beds but during the last eight years only seven cases have been isolated therein. Nuremberg has a small-pox pavilion with 12 beds but there has been no small-pox in the town for the last 11 years. When cases of small-pox are isolated at the general hospitals no panic occurs—there is no incidence of the disease upon the surrounding population. The immediate attendants upon the sick are again revaccinated but with respect to the general staff and to the other patients reliance is placed upon the general routine vaccination and revaccination of the people. How different is all this from the conditions which obtain in this country, with its repeated instances of the excessive incidence of small-pox upon the houses in the neighbourhood of the small-pox hospitals and the costly machinery necessary to obviate such occurrences. And yet, few if any persons, conversant with the history of small-pox in London and of the influence of the small-pox hospitals, would venture to suggest that with our present very imperfect protection by primary vaccination alone London should again "isolate" its cases within its own limits.

At every place visited by Dr. LOW inquiries were made as to any spread of the disease and as to the reasons for the immunity of the surrounding population and in every case the answer was in the negative and the explanation of the immunity of the population surrounding the hospital was the protected character of the German people. It is to be hoped that the result of this report will not be to relax our own precautions as to the isolation of small-pox without at the same time insisting on a general revaccination of the population. To do this would be a fatal step. We emphasise this knowing that those who are not familiar with the history of small-pox hospitals in this country will use this report by Dr. LOW as a justification for relaxing necessary precautions. But Mr. LONG may be trusted not to give way and he may, we hope, also be trusted to introduce a Bill for general revaccination so as to put an end to the costly methods of isolation practised in this country, leaving the disused small-pox hospitals for the use of the tuberculous sick or for the reduction of some other preventable diseases. Both he and Mr. W. H. POWER, the medical officer of the Local Government Board, are to be congratulated cordially upon their initiative in this matter and Dr. LOW is to be felicitated upon his instructive report. We only wish that the Local Government Board evinced more frequently this high appreciation of its imperial duties in a public health sense. The medical department of the Board is largely concerned in advising other Government departments in matters of public health and it is surely incumbent upon the Board to keep abreast of modern methods by ascertaining precisely what is being done in other countries. The British empire has responsibilities in a moral as well as a martial sense. In matters such as these all depends upon the initiative, upon the grasp of the principle of expansion which is possessed by successive presidents.

Mr. LONG is apparently at the present juncture thinking imperially in a public health sense. He has despatched

---

[1] Dr. R. Bruce Low's Report to the Local Government Board on the Arrangements made in Germany for the Isolation of Small pox Cases. Eyre and Spottiswoode, East Harding-street. 1904. Price 1s.

Dr. Low to Germany and the report now under notice is the result, and he has also despatched Dr. Theodore Thomson to the West Indies with the view of ascertaining how far the methods of dealing with cholera and plague in vogue in these parts of the empire can be brought more in line with the practices of the mother country. If the Local Government Board is to advise upon these matters it is obviously desirable that some of its staff should be familiar with the several localities which from time to time are brought in question.

◆

The Control of Measles.

Nearly eight years have elapsed since the publication of Dr. Theodore Thomson's classical report to the Local Government Board upon measles. There are still, however, very few sanitary authorities who have set about the task of dealing with the prevention of this disease in anything like a systematised manner, although Dr. Thomson stated in his communication to the Board very definitely what in his opinion were the measures which were necessary to prevent the extension of an epidemic throughout an invaded district. The cause of this inaction was frankly admitted by several speakers at the last meeting of the Incorporated Society of Medical Officers of Health in the course of a discussion initiated by Dr. J. Howard Jones upon the best means of controlling outbreaks of measles, an account of which was published in The Lancet of April 16th, p. 1058 The difficulties which beset the medical officer of health who is called upon to deal with this disease are undoubtedly in the first place its highly infective character, especially in the early stages and before definite symptoms have manifested themselves, and, secondly, the demeanour of the general public who regard the disease with indifference and even with contempt. There are other reasons to account for the non success of such preventive measures as have up to the present been adopted and chief among them, as pointed out by Dr. Arthur Newsholme, is this, that we are deficient in a knowledge of facts relating to the behaviour of the disease. For example, we do not know with any degree of certainty how long a person may be infectious after an attack of measles, nor do we know definitely for how long the contents of rooms occupied by a person who has been suffering from measles may be capable of retaining the infective material. There are, indeed, some epidemiologists who deny that the disease may be spread by fomites at all and if they are right there must be an utter waste of public money in those districts where large sums are being spent in the disinfection of dwellings recently occupied by sufferers from measles. Now that the Education Acts are being administered by public authorities, many of whom have the advantage of including among their permanent officials a medical officer of health, questions such as those which we have indicated will no doubt be much more closely investigated than has hitherto been the case, and it is to be hoped that the education committees will give every facility to those medical officers of health or medical officers of schools who desire to study the subject. There is still another obstacle in the way of the successful suppression of epidemics of measles but it is one which ought to be capable of an easy and speedy removal. We refer to the prevention, through the instrumentality of Section 126 of the Public Health Act, 1875, or of Section 68 of the Public Health (London) Act, 1891, of infected persons being wilfully exposed in public places. These sections enact that any person who while suffering from any dangerous infectious disorder wilfully exposes himself without taking proper precautions against spreading the disorder in any street, public place, or the like, shall be liable to a penalty of £5 During the past few weeks correspondence has been taking place in The Lancet as to the interpretation of the words "dangerous infectious disorder" in these sections. One of our correspondents in the West of England gave an account of the action taken by a medical member of the Bath town council with regard to a circular notice issued by the medical officer of health of Bath to the effect that a person is liable to a penalty who wilfully exposes himself in a public place while suffering from measles. Our correspondent stated that the medical councillor in question was evidently of opinion that Section 126 does not apply to measles, whereupon Dr. Preston King, who was the medical gentleman alluded to, replied in a subsequent issue that it was not a question of opinion but of fact, and that the expression "dangerous infectious disorder" in the Act of 1875 applied only to the scheduled infectious diseases in the Infectious Disease (Notification) Act, 1889. Exception was taken to this interpretation by other correspondents and at the meeting of the Society of Medical Officers of Health already referred to the question was discussed by several speakers, some of whom insisted very strongly that Section 126 applied to any dangerous infectious disease, including measles, while others were equally emphatic in their opinion that the section referred only to those diseases scheduled under the Infectious Disease (Notification) Act, 1889. So far as we are aware there are no records of any prosecutions for wilful exposure while suffering from measles, though we believe one such successful prosecution was once undertaken by the medical officer of health of Wigan. It is very desirable that there should be a decision on this debateable question in a court of law and there should not be any difficulty in obtaining a definite pronouncement.

◆

The Cholera and Enteric Fever Epidemics at Hamburg.

It would seem as if Hamburg is destined to remain for many years to come the classic ground of discussion on the action of water in the spreading of such diseases as cholera and typhoid fever. This subject was brought forward again before the Epidemiological Society at its last meeting, when Dr. Reincke, who is a corresponding member of this society and medical officer of health of the city of Hamburg, read a paper on the Epidemiology of Enteric Fever and Cholera in Hamburg, which is published at p. 1105 of our present issue. There is a curious feature about discussions in regard to Hamburg. Almost all those who enter into the details seem to come under a sort of spell. It would appear as if the mere name of Professor Koch exercised a magic power and blinded them to a large number of important considerations which happen not to hold a prominent place in the remarkable and fruitful studies of this eminent man of science. One or two passages in Dr. REINCKE'S paper read as if he was striving to shake himself free from this influence, but he does not succeed in doing so for long. For instance, he commences by saying that it is necessary to have "a clear picture in one's mind not only of the topography of the town but also of the topographical arrangement of the surrounding district." Nevertheless, and in spite of this very correct and emphatic pronouncement, Dr. REINCKE himself omits the most remarkable topographical feature of the picture.

The salient peculiarity that meets the eye on reaching Hamburg is the fact that a great part of Altona is built on a hard rock or cliff, while Hamburg lies below on flat soil a great portion of which has been redeemed from the bed of the river Elbe. The fact that Altona and Hamburg have not the same water-supply is always insisted upon and then the statistics of Altona and Hamburg are compared. But what is required is a more detailed study as generalisations may lead to error. Dr. REINCKE recalls the main facts in regard to the cholera epidemic of 1892 and says that at Hamburg "there were 26·42 cases per 1000 inhabitants and 13·44 deaths per 1000, whereas in Altona these numbers were 3·81 per 1000 and 2·13 per 1000 respectively." Then he quotes the spotted map where the spots marking the cases of cholera stop when they approach the demarcation line which separates the townships of Hamburg and Altona. But we are not told that it is precisely those parts of Hamburg that are built on the marsh land close to the river that suffered the most, and that it is precisely the part of Altona which is nearest to the river which is built on a rock. This rock forms a sort of river wall and is almost perpendicular in some places. It is quite natural that the spread of cholera should be checked at the foot of a cliff. Near Toulon and other places the same phenomenon has been noted. It would be very useful to make a fair comparison between Altona and Hamburg but it has not yet been done, though it does not seem to be altogether impracticable. There are at Altona, away from the river and behind the rock, some low-lying and poor districts that do compare fairly with what exists at Hamburg. If the statistics from these districts could be secured it would be found that the death-rate from cholera in that part of Altona was very much higher than 2·13 per 1000. Thus the contrast between Altona and Hamburg would not be so great as stated, and this, too, in spite of the difference of the water-supply in the two places. In any case, and as we have on more than one occasion pointed out, the contrast between Altona and Hamburg is not so great as that presented within the boundaries of Hamburg itself, where there is no difference in the water-supply. This is admirably set forth in the statistics of the Hamburg municipality. Here it is shown that in the Harvestehude district, where the average annual income is 3155 marks per head, the death-rate from cholera was 4·48 per 1000. On the other hand, in the Veddel district, where the annual average income is only 118·93 marks per head, the death-rate from cholera was equal to 27 50 per 1000. With these figures it would be as logical to say that the epidemic depended on the money-supply rather than on the water supply but this would be only a part of the truth. Not one but many factors must be taken into account. Let us take the Hamm district where the income is not very high or very low—namely, 716·7 marks per head. It will be found that on the portion of this district which rests on dry soil the death-rate was 9·15 per 1000, while in the part which is built on marsh land the death-rate from cholera was 21·37 per 1000. Here we have a small district, all the inhabitants drinking the same water, and yet what a different result.

Though admitting that enteric fever follows much the same rules as those which govern the spread of cholera Dr. REINCKE is less affirmative in regard to the action of water. He states that this question cannot be decided statistically because the numbers involved are too small. Then when speaking of the forthcoming supply of absolutely pure water from deep wells he adds this significant warning: "What enteric fever then remains will certainly have nothing to do with the water-supply. Already now I should like to remark that several large towns of Germany supplied with deep well water have not less enteric fever than Hamburg." Further, he adds, "you will see clearly that the great epidemics of enteric fever fall in the dry years when there is a low level of ground water, whereas in very rainy years enteric fever obviously recedes." Not that Dr. REINCKE supports PETTENKOFER'S theories; on the contrary, he tries to show that it is in these dry seasons that the water-supply is most likely to be contaminated. Thus we are forced back upon the previous admission that typhoid fever is as prevalent in towns where the water-supply is above suspicion as it is in Hamburg where the water has so often been accused as the cause of all the mischief. The real fact is that contaminated water, just like contaminated milk, is a very efficient means of spreading enteric fever among persons who are predisposed. If there is no such general source of dissemination of infection then these diseases will spread more slowly. But where the population is predisposed to the disease it will find some door of entry. The only complete remedy is to remove the predisposing causes. They are of more importance than the accident that spreads the epidemic and of these predisposing causes Dr. REINCKE, in company with too many authorities on such subjects, fails to give us any information. Nevertheless, the presence of such an eminent authority among us is a great advantage. There is much to be learned from the experience acquired on the continent, and the Epidemiological Society is to be congratulated on having secured the coöperation of Dr. REINCKE.

Annotations.

"Ne quid nimis."

STATISTICS OF TUBERCULOSIS.

Dr. G. A. Heron delivered a lecture on April 14th in the school-room of St. James-the-Less in Sewardstone road, Victoria Park, London, on the Prevention of Consumption. The lecture was given at the invitation of the Kindred Working Men's Hospital Supporting Societies and Dr. Heron had no reason to complain of the enthusiasm of his audience. Some interesting statistics were furnished to Dr. Heron by Dr. John Tatham of the General Register Office, Somerset

House. The fall in the mortality from phthisis was well shown in the following table :—

Death-rate from Phthisis in England and Wales per 1,000,000 Living (Both Sexes).

Five years, 1866–70.	Five years, 1871–75.	Five years, 1876–80.	Five years, 1881–85.	Five years, 1886–90.	Five years, 1891–95.	Five years, 1896–1900.
2448	2218	2040	1830	1635	1462	1323

In a period, therefore, of 35 years the fall in the mortality from phthisis has been from 2448 per 1,000,000 to 1323 per 1,000,000. According to Dr. Tatham the mortality from phthisis differs greatly in the two sexes. In the last five years for which statistics have been prepared—i.e., in the quinquennium 1898–1902—phthisis was fatal to 1529 out of every 1,000,000 males living but to only 1114 females in every 1,000,000 females living. Dr. Heron also communicated the following important table from Dr. Tatham :—

Annual Death-rates from Phthisis per 1,000,000 Living Persons in England and Wales.

Year.	Death-rate per 1,000,000.	Year.	Death-rate per 1,000,000.
1882	1850	1893	1466
1883	1880	1894	1383
1884	1827	1895	1395
1885	1770	1896	1303
1886	1739	1897	1336
1887	1615	1898	1311
1888	1563	1899	1330
1889	1573	1900	1333
1890	1682	1901	1264
1891	1599	1902	1233
1892	1468		

Another table furnished by Dr. Tatham dealt with the infantile mortality of tuberculosis.

Annual Rate among Infants under One Year in each 1000 Births.

Years.	Boys.	Girls.	Both sexes.
1897–1901 (average)	8	6	7

Annual Rate among Children under Five Years in each 100,000 Living at that Age.

Years.	Boys.	Girls.	Both sexes.
1897–1901 (average)	395	320	357

Dr. Heron wisely avoided entering on debatable points in connexion with the subject upon which he was lecturing and laid great stress on the fact that the power to move in the matter of securing the prevention of consumption lies in the hands of those who vote for Members of Parliament. He also urged his hearers to procure from candidates for Parliament at the next general election definite pledges to promote further legislation for public health. He particularly indicated the advisability of educating the public to a proper appreciation of the precautions necessary to prevent the spreading of consumption.

THE ASTLEY COOPER PRIZE.

As will be seen by an advertisement in the present issue of THE LANCET the next triennial prize of £300 under the will of the late Sir Astley Cooper, Bart., will be awarded to the author of the best essay or treatise on the Naked-eye and Histological Anatomy of the Spinal Cord. The competition is open to everybody except the members of the staffs of either Guy's Hospital or St. Thomas's Hospital or any one related by blood or affinity to them, but the essays must not be the production of two or more authors. They must be written in English or if in a foreign language must be accompanied by an English translation and they must be sent to Guy's Hospital on or before Jan. 1st, 1907, addressed to the Physicians and Surgeons of Guy's Hospital, London, S.E. The successful essay may be printed in the Guy's Hospital Reports but this will not preclude the author from publishing it elsewhere after obtaining permission. Further particulars as to the conditions of competition and the like may be obtained on application to Dr. G. Newton Pitt, Guy's Hospital, London, S.E.

THE MOISTURE IN TOBACCO.

THERE may be good fiscal reasons for raising the degree of moisture in tobacco from 30 to 32 per cent., as is suggested in the new Budget, but the precedent, we think, is an undesirable one and the principle of the proposal open to objection. To pay 5*s.* a pound for water in tobacco may not appear to be on all fours with paying 5*d.* a quart for water in milk, or 1*s.* 6*d.* a pound in butter, but morally there is no difference. The State allows it in the first case but not in the second and third. The old limit as regards tobacco was liberal and worked satisfactorily and on the whole there is reason for opposing a policy of State-aided attenuation. Moreover, it may be remarked that the presence of moisture in tobacco is of some importance to public health, since the combustion of tobacco containing a large proportion of moisture is impeded, while as the generation of vapour is increased so are the chances of the poisonous principle being carried into the mouth.

SAMUEL SMILES.

AT the ripe age of 92 years Dr. Samuel Smiles, whose name has been a household word in British homes for 50 years, passed away last week. Born in a comparatively humble sphere of life he succeeded by sheer hard work, and by carrying out the precepts which he laid down in his books, in raising himself to an important position in the railway world, while his literary reputation was a doubly important one, for he was both an enormously successful author and a writer of most healthy influence upon the character of the English race. At the age of 20, when the General Medical Council had not been invented and medical curriculums were less strict, Smiles became qualified to practise medicine and started practice in his native town of Haddington, but patients being few he forsook his calling and studied music and painting, supporting himself in the meanwhile by writing articles for the press. In 1837 he became the editor of the *Leeds Times*, on the strength of which appointment he married, but after his marriage, finding his salary too small for his domestic requirements, he gave up the post and became assistant secretary to the Leeds and Thirsk Railway. Later he became secretary to the South-Eastern Railway Company, a post which he left in 1866 to become secretary to the National Provident Institution. These positions brought him into contact with the men whose lives formed the text for some of his best books. One of his earliest works, "Physical Education, or the Nurture and Management of Children," no doubt owed its being to his medical studies but "Self Help," the work by which he is perhaps best known, "Thrift," and other similar books were based upon lectures and addresses which he delivered before young men's debating and mutual improvement societies. Possibly the secret of the enormous popularity of these works—and until recently they were the most usual prize in the lower forms of every school in the kingdom—lay in the fact that the manuscripts had been used to lecture from, so that the author was able to revise them in a very practical way. He knew which were the passages that were effective and where to make his deletions, which is another way of saying that he learned the art of composition. The life of Dr. Smiles, whose doctorate was LL.D. given to him by the University of Edinburgh, well illustrated the principles of industry and integrity which he has inculcated into so many of his younger countrymen.

THE SHAKING OF THE DOOR-MAT.

THE mat at the front door is necessarily the receptacle of all kinds of filth picked up from the streets. In dry weather there is little use for the mat but in wet weather all cleanly disposed persons use it. The time comes when the mat is loaded with dirt in a more or less dried state and the simplest way of removing the burden of dirt is to submit the mat to shaking, generally on the curb-stone, or to bring it into sharp contact with a wall. This is the *modus operandi* generally adopted much to the annoyance and discomfort of the passers-by. Frequently a most offensive cloud of dust is thus raised and that this can be a source of ill-health cannot be disputed. The street door-mat must teem with potentialities for evil having regard to its purpose. The method of shaking dirty mats in the face of the pedestrian in the street is an offence against decency and hygiene and the local authorities should take steps to suppress the objectionable practice. If this clumsy method cannot be altered the mat should be taken to a place where the evil dust would affect nobody and every endeavour should be made to localise the cloud of dust. The beating of carpets is another necessary evil which, however, we do not allow in our streets, and yet most probably the dust of the more privileged door-mat would show a much more dangerous bacteriological flora than the carpet.

OVARIOTOMY AND HYSTERECTOMY IN MARTHA WARD, ST. BARTHOLOMEW'S HOSPITAL, DURING THE YEARS 1897–1903

IN the St. Bartholomew's Hospital Reports, Vol. XXXIX., an interesting paper is published by Mr. Harrison Cripps on Ovariotomy and Hysterectomy in Martha Ward during the years 1897–1903. In these six years 182 ovariotomies have been performed, with a mortality of 2·7 per cent., and 58 hysterectomies, with a mortality of 6·8 per cent., or a total of 240 cases of ovariotomy and hysterectomy, with a death-rate amounting to 3·7 per cent. These operations are performed in a special theatre and the improved results of the last six years are attributed by Mr. Cripps to the use of the Trendelenburg position and the employment of biniodide of mercury as an antiseptic. Drainage is very seldom used and the abdomen is flushed out and drained only in those cases where there has been some escape of pus or fæcal matter into the abdominal cavity. In place of the thick silk that was at one time in use No. 2 Chinese twist is now employed and with this pure silk a ligature sinus very seldom occurs. In the performance of abdominal hysterectomy the cervix is usually left and any bleeding from the stump is checked by the use of the actual cautery at a heat of a little above that of boiling water only. Mr. Cripps likes to use both sponges and pads; the latter are made of soft woven cellular wool, are about half an inch thick, and are of a diameter varying from four inches to 14 inches. In closing the abdominal wall he uses large curved Hagedorn's needles and passes the sutures through the whole thickness of the wall including all the tissues. He has discarded the plan of sewing up the abdominal wall in layers after having given it a thorough trial. This report calls attention to the fact that St. Bartholomew's Hospital is one of the few remaining hospitals in which the physician accoucheurs are not allowed to perform abdominal operations in cases of disease of the pelvic organs. All the cases in which an abdominal section is considered necessary are seen by one of the surgeons, at the present time by Mr. Cripps, and if an operation is decided upon he performs it and takes subsequent charge of the case. We must say that we fail to see any valid reason for the continuance of this obsolete custom. We are quite prepared to admit that the question as to whether obstetric physicians should be allowed to operate at all or not is one upon which there may well be much difference of opinion. If they are to be allowed to do so then they should undoubtedly have had a proper surgical training. To allow the obstetric physicians at a hospital like St. Bartholomew's to perform operations upon the vagina and not to allow them to perform abdominal sections appears to us to be absurd. The removal, for example, of the uterus and appendages by the vagina in a case of chronic pelvic suppuration is often a much more difficult and dangerous operation than the great majority of ovariotomies and hysterectomies. To permit an obstetric physician to perform such an operation or to carry out a Cæsarean section and to forbid him to perform abdominal ovariotomies and hysterectomies is a prohibition which appears to us to be unreasonable.

THE HOLMAN TESTIMONIAL.

DR. Holman, whose devoted service in behalf of the medical profession is to be recognised suitably, has been for the last 50 years a strenuous worker in public and private capacity. His career was largely shaped by the influences under which he fell at the beginning of his medical course. In accordance with the recognised professional education of his day he commenced his curriculum as an apprentice to Messrs. Thomas and Peter Martin, a firm of medical practitioners in Reigate. Mr. Thomas Martin aided Sir Charles Hastings in the foundation of the association which was later to be known as the British Medical Association, and Dr. Holman aided his principal. He at the same time acted as assistant secretary to Mr. Martin at the Surrey Medical Benevolent Society where, in 1848, he met Propert, the founder of Epsom College, so that while still *in statu pupillari* he became connected with the three institutions to which he has given up so much of his life. In due time Dr. Holman proceeded to Guy's Hospital, where he won prizes, served under distinguished men, and made many friends. After qualifying and a course of study at Edinburgh and Paris, he settled in Reigate in 1852 and was appointed joint secretary of the South-Eastern branch of the British Medical Association, the branch of which later he was secretary and president. Dr. Holman has done yeoman's service for the British Medical Association. He was treasurer at a critical time in the Association's history and chairman of the editorial reference committee which was appointed during the later period of Mr. Ernest Hart's editorship and which was discontinued when Dr. Dawson Williams became editor. He was also on the premises committee and has seen the acquirement by the Association of its freehold property. For these services Dr. Holman was made a vice-president for life, though the reconstitution of the Association deprived him of his seat on the Council. In 1887 he was elected treasurer to Epsom College. His services to this last institution will be apparent when we remind our readers that in 1887 the school was in debt to the amount of some £7000 and that this debt has now been wiped out, although—we mention this lest we should impede the flow of donations—there is still a mortgage on the property of £10,000. In addition to these multifarious works Dr. Holman carried on a large practice at Reigate, founded the Reigate Cottage Hospital, started a dispensary to which every medical man in the borough belonged, and served on the town council and was the first magistrate to be sworn in on the borough bench. This is a record of good work and Epsom College particularly owes to Constantine Holman a debt which can hardly be paid. It is fitting, therefore, that the testimonial about to be raised for him, further subscriptions to which are acknowledged on p. 1172, should in some way increase the influence for good of the foundation of that institution. Dr. Holman was recently elected an honorary member of the Medical Society, a compliment that is not often paid to British medical men.

THE REGISTRATION OF NURSES.

AT a meeting of the executive council of the Association of Poor-law Unions of England and Wales on April 12th the parliamentary committee of the council, which has had under consideration the Nurses and Private Nursing Homes (Registration) Bill, reported briefly that it disapproved of the measure since it believed that its passing would have a prejudicial effect on the supply of probationers for Poor-law nursing. This opinion is noteworthy as supporting the manifesto to which we had occasion to refer in THE LANCET of April 2nd (p. 946) and might, if it stood alone, be accepted as confirming the position of those who object to State registration. At the same meeting, however, a discussion on workhouse nursing took place which may be taken to indicate the train of reasoning by means of which the above verdict was arrived at and we are fain to admit that whatever merit there may be in the conclusion the premisses are wofully lacking in appreciation of the true interests of the nursing profession. After a long debate the following propositions were adopted by large majorities:—

1. That the minimum age for commencing training should be 18 years.
2. That "qualified" nurses as distinct from fully certificated nurses should be recognised.
3. That an infirmary without a resident medical officer may yet be a training school for nurses.

Stronger evidence of the necessity for erecting some definite and suitable standard of technical education, conformity with which should alone justify the employment of the term "nurse," could hardly be tendered. But will the Bill now before the House of Commons supply that standard? There is ample ground for thinking that it will not. In so far as it admits the advisability of intrusting the registration of nurses to an independent authority rather than to any chartered corporation of nurses the Bill is a step in the right direction. Everything, however, turns upon the constitution of the central board which is to be formed, and it may be said at once that the board described in Section 4 is not of a kind to inspire confidence. In the first place, the women on the board will be at least in the proportion of 2 to 1; indeed, it would be quite consistent with the Bill to have none but female members. Now, many persons hold that women rarely display that capacity for mutual concessions which makes for a united policy. Although it is of the first importance to the efficient performance of a nurse's duties that she should be under the direction of the medical practitioner whom she is supposed to be assisting, the Bill requires that only three members out of the 21 making up the board should belong to the medical profession. The result will inevitably be the removal of medical supervision from the training and examination of nurses and the reduction of the medical man to a subordinate position in the control of the wards of hospitals and infirmaries. This consideration applies more particularly to Poor-law institutions under medical superintendents. As far as the hospitals supported by voluntary subscriptions are concerned there can be little change in this respect since in them the matron already exercises a preponderating influence and faithfully exacts her tribute of deference from staff and students. While the definition of a "nurse" given in Section 17 covers both men and women it is quite clear that nurses of the former sex will have no voice in the management of affairs and we are promised the anomaly of a council dominated by women attempting to regulate the training of a body of men whose *raison d'être* is the very fact of their undertaking work which women are not thought competent to perform. It is further to be noted that such a large employer of labour in the way of nursing as the Metropolitan Asylums Board has no direct influence in deciding upon the claims of various persons to the style and title of "nurse," and more remarkable still is the fact that no allusion is made in the Bill to the Local Government Board which is, in effect, the court of appeal in nursing matters for the large body of men and women, constituting a majority of nurses, who work under the Poor-law. Another point is perhaps worthy of attention. No provision is made to remove that ambiguity attaching to the word "person" which has so often given rise to trouble. There appears to be nothing to prevent the formation of "nursing companies" by unqualified individuals who could set the Bill, if passed, at defiance, just as has been done in the case of druggists and dentists. Altogether the Bill is unsatisfactory and since it has little prospect of passing this year it is to be hoped that drastic changes will be made in it if it is to be again introduced.

THE NAUHEIM SPRINGS.

THE paper read before the Hunterian Society on March 23rd by Dr. Paul C. Franze on the physiological action of the Nauheim springs and the indications for their use chiefly in circulatory disorders once more directs the attention of the medical profession in this country to the value of those springs in the treatment of affections of the heart and blood-vessels. The first effects produced on entering a Nauheim bath are acceleration of the pulse and contraction of the peripheral vessels of the skin and subcutaneous tissue. Congestion of the internal organs ensues; soon, however, the contraction ceases, the superficial vessels dilate, and the pulse becomes slower and stronger; "reaction" is manifest. Dr. Franze considers that the presence of the salts in solution and the carbonic acid gas intensify the stimulation of the skin and modify the action of the coldness of the water, the aggregate result being that in a Nauheim bath reaction supervenes much sooner and with a greater intensity than is possible with ordinary fresh water. Many authorities on balneology consider that the salts in solution in the various mineral waters are not absorbed by the skin to any appreciable extent. Dr. Franze, however, whilst admitting that it is improbable that any salts completely permeate the skin, believes that they are imbibed by the epidermis to a sufficient extent directly to stimulate the peripheral nerve endings and capillaries of the corium. The salts then maintain their action for some time after the conclusion of the bath. The entire nutrition of the skin is thus increased, it holds a greater amount of blood, and its excretory functions exhibit a revivification which is more than transitory. It must be acknowledged that as yet no scientific basis for balneo-therapeutics has been established but it must nevertheless be granted that special bathing and drinking "cures" are most efficacious in many chronic morbid conditions and cannot be replaced by any other modes of treatment. We venture to suggest, however, that the good results often obtained at Nauheim in patients suffering from chronic cardiac affections cannot altogether be assigned to the virtue of its waters. Patients may purchase "salts" brought from Carlsbad or other spas, dissolve them, and drink the solutions in their own homes in England but they will not experience the same beneficial effects as from a course of treatment at one of those spas. The difference is that at the continental resort the patient is subjected to a *régime* which is highly beneficial. So it is at Nauheim. The hour of rising, the time, quality, and quantity of meals, the journey to and from the bathhouse, and particularly the amount and nature of exercise are most carefully regulated. Cases of "cardio-vascular neurosis" are especially favourable cases for treatment at Nauheim and doubtless the strict *régime* under which they are placed has much to do with their recovery. It is exceedingly difficult, if not impossible, to impose the same restrictions upon these patients in their own homes; they are therefore sent to Nauheim for a special purpose and devote all their energies to "getting well."

SPRING SLACKNESS.

THERE are certain persons to whom the advent of spring, instead of bringing that sense of rejuvenescence which was referred to in an annotation in our columns last week, provides a very different sensation. The youth of the year, when nature seems to revel in growth and development, ought to give, it might be thought, to the human species too a sense of vigour and of the natural joyfulness of fecundity. When the birds are breaking into song and the plants into flower poor man might also exult in life and its annual time of awakening growth. Yet to many the return of spring is only the return of a vague feeling of listless languor, a slack sense of fatigue that comes without labour and of weariness that is uncalled for by any unusual effort To those who dwell in cities, at any rate, spring has trials that are peculiar to itself. To some extent these arise from the knowledge that abroad in the country all is new life, refreshened vigour, and inspiring atmosphere, while in town the wonted thraldom is enhanced by the suspicion of these things that is gained from the trees and the plants of public parks and open spaces, where poor little bits of nature bloom only to suggest in vain all that awaits the town dweller if he could escape. It is not only dissatisfaction though at being unable to partake in nature's gaiety that produces the feeling of which we speak: something is due to climatic conditions. Who does not know the enervating sense that accompanies the first warm day of the year. We may agree with Johnson that he is a weak creature who is influenced by the weather but if we do we must confess with the same breath that to-day most of us are weak creatures. If, like Johnson, we lived in more leisurely times and regaled ourselves heartily in Fleet-street about the middle of the day, following the meal with a comfortable discussion, maybe we, too, should be indifferent whether the sun shone or the rain fell. Unfortunately we work our nervous systems more and our alimentary organs less than did our grandparents. Inevitably we have a sensitiveness that was unknown to most of them. Their fits of "the spleen" were well earned, probably, by loads within the stomach. We acknowledge no such consoling cause for the ennui that often in the spring assails the town dweller. Happy he who can dispel it by a week-end in the country or at the sea before his regulation summer holiday arrives.

THE DISTRIBUTION OF PLAGUE.

THE medical officer of health of the Cape Colony reports that for the week ending March 26th the plague state of the colony was as follows. No case of plague in human beings was discovered at any place in the colony during the week in question but plague-infected rodents were found at Port Elizabeth and at East London. In the Cape Town and Harbour Board area 302 rats were examined during the week but none was affected with plague. As regards the Mauritius, a telegram from the Acting Governor received at the Colonial Office on April 15th states that for the week ending April 14th there were 2 deaths from plague. With respect to the Transvaal a telegram from Lord Milner, dated April 16th, states that the suspected cases up to that date numbered 158: coloured persons, 140; and whites, 18. Deaths 75: coloured persons, 68; and whites, 7.

THE PRODROMATA OF THE PSYCHOSES.

AN interesting article on the prodromata of the psychoses and their meaning is published by Dr. T. S. Clouston of Edinburgh in the *Journal of Mental Science* for April. It is a fact of psychiatric medicine not sufficiently recognised, says Dr. Clouston, "that attacks of mental disease have early symptoms that are often not mental in character and it is equally true that in neurology the fact has not attracted sufficient attention that all sorts of sensory, vaso-motor, and motor symptoms may be the mere preludes to an attack of insanity and not be of themselves the real disease." Such prodromata are important because the recognition of their true character might enable us in many cases to anticipate and possibly to ward off the mental attack. The practitioner who is called to see a woman suffering from an unusual form of headache, with anorexia, insomnia, and obscure paræsthetic sensations, often misses the real point of the case because he does not realise that such symptoms are, in this particular patient, of higher cortical origin and may mean an attack of acute mania in a week if nothing can be done to arrest their course. The occurrence of a widespread disorder of action of the highest cortical nerve centres, such as underlies an attack of acute insanity, affects almost of necessity the sensorial, vaso-motor, and nutritive functions of the brain and the body. Often the indications of oncoming disease are shown by disturbance of such functions accompanied with insomnia for some time before insanity is developed. Of the sensory disturbances headache and obscure cephalic pains and sensations (paræsthesiæ) easily set up by slight causes are of warning import. Indigestion, worry and anxiety, mental over-fatigue, constipation, and slight alcoholic excess may be exciting causes of such disturbances and may lead to slight or severe, but usually not serious, "nerve storms." The persistence of insomnia and of melancholic depression makes the outlook a little more serious. Dr. Clouston reports a typical case of a woman, 50 years of age, who had been subject at times to headache and a "weary," painful feeling in the back of her neck and back all her life when tired, but who otherwise was strong and well-nourished. During a period of special anxiety and much exhausting nursing which she had to go through these head and spine symptoms got worse and became continuous instead of being intermittent. They unfitted her for work, mental or bodily, and she had to remain in bed all day. There was neither rise of temperature nor local tenderness. Their persistence exhausted her strength and brought on insomnia and in a few weeks she became depressed mentally. "When the melancholia came on all the bodily pain went off. In the course of three months she was acutely melancholic and had to be placed in a mental hospital for treatment. She recovered but the first symptom of the passing off of the psychosis was the recurrence of the headache and bodily pains." She has had several such attacks since, each one with the same sequence of symptoms. She has now the impending feeling of danger and dread which so many melancholiacs have before an attack. This case is a type so commonly met with, says Dr. Clouston, as to cover very nearly half the field of melancholia. In most cases the headaches have not quite the character of the ordinary "woman's headache," they are more constant and intense, more distracting and disabling, and attended with "peculiar sensations" as of weight, lightness, local burning, or "bursting." Often they are accompanied by giddiness, creeping feelings, and sensations of heat and cold, and of soreness about the head. Dr. Clouston looks to a nutritional failure of the higher cortical nerve cells as the cause of such symptoms. Auto-intoxication, if present, aggravates the condition but is as likely to be a sequel facilitated by the lowering of the vitality of the brain and the nervous system. The mental areas or centres in the brain, says Dr. Clouston, are "like a busy city on an island, its food, its commerce, its electric wires, and every source of its life and activity being carried to it through the surrounding sea." The sensory paths, the gateways into the mind, are first disturbed and melancholia or mania, stupor or mental dissociation soon follows. "An over-sensitive constitution is commonly the basis of the melancholic diathesis." Visceral paræsthesiæ may be the starting points of delusional conceptions developed in melancholia. The facial muscles of expression are the first to fail in subtlety and beauty of coördination and before the mind gives way the eye is dull or listless or the cornea has the feverish light of oncoming mania. The brow is furrowed, fixed "lines of care" show themselves on the face, there is often an "abstracted" look, and the lively play of features characteristic of health is lost. Neurasthenia, insomnia, hysterical attacks, circulatory disturbances such as palpitation, "sinking at the heart," and attacks of flushing hot and cold, long precede the mental symptoms. We know little about blood changes because they have not been investigated in the prodromal stages and the same may be said, concludes Dr. Clouston, of the so-called auto-intoxication processes. Menstrual derangements are frequent prodromata of attacks of insanity in women, amenorrhœa being particularly common.

THE CRY OF PAIN.

No chapter in the book of natural science is more interesting than that which deals with the emotions of human beings and of animals, how they are aroused and how they are exhibited. Indeed, so far as man is concerned, it may almost be said that this study lies at the bottom of every art. To depict the emotions of his imagined beings and thus to arouse through sympathy the real emotions of those before whom they are depicted is the aim alike of the artist, the author, and the actor. Nor is there anyone amongst an audience at the theatre or amongst the readers of romance or the spectators at a picture gallery who is better able to value an artist at his real worth than the student of natural history who has looked a little into this matter of the emotions and has studied their origination and the true symptoms by which they are displayed in nature. Thus, too, it often happens that the painted picture of some human struggle or the artistic efforts of a sensational actor may appeal to the vulgar eye but through some obvious flaw in correct expression or in muscular action may fail to impress the more discerning eye of the biological student or the trained medical man. Emotion forms, even in the materialistic times of to-day, so large a portion of life, and we are all so ready to read in outward expression the emotions which move in other breasts, that the essential nature of the expression of emotion is easily lost sight of. We forget that all such expression is probably primarily a subjective affair. Emotion is given expression to not that another may be thus affected but that he who experiences the emotion may find relief in the expression to which he gives vent. It is this subjective side of the matter that our correspondent "Psychologus"[1] draws attention to in alluding to the value that the cry of pain possesses in consequence of reaching the ear of him who utters it. Nevertheless, it is not actually the hearing of the cry that is essential. The sufferer would be equally relieved if his ears were stopped and he did not hear his own cry, so long as he was conscious of performing the muscular exercises that should result in such a cry. What is required for the relief of his sufferings is violent expenditure of nerve force. Nature provides this in violent muscular action and this is performed along habitual lines. Darwin, in his "Expression of the Emotions," deals with this point and we cannot do better than refer our correspondent to p. 76 of that delightful work, although we have not succeeded in finding there or elsewhere any explanation directed pertinently to the exact point which he brings forward. Yet our correspondent will find in the book much cognate information and, supposing him not to be already familiar with it, much that is suggestive of the elucidation for which he is inquiring.

TREATMENT OF INGUINAL HERNIA BY EXERCISES.

In the *Yale Medical Journal* for February Dr. Jay W. Seaver recommends exercises in the treatment of inguinal hernia in the young, a method which does not appear to have received attention previously. The *rationale* of the treatment is obvious; the inguinal canal is surrounded by muscles which the more they are developed the more they resist the passage of any of the abdominal contents. Dr. Seaver finds that of college students nearly 3 per cent. have indirect inguinal hernia and that other forms of hernia are very rare. Physical examination of the Yale students showed that in only about 16 per cent. of those suffering from hernia was a truss worn; many were unaware of the existence of the hernia. By practice a patient can acquire the power of contracting particular parts of the abdominal wall. Almost any person can in a month learn to contract the lower abdominal wall near the pubic arch and can make this contraction pass as a wave up the abdominal wall. Or one side of the abdomen may be contracted and then the other. The following are some of the exercises which Dr. Seaver recommends. They are performed twice or thrice daily for from five to eight minutes. 1. Lying on the back on a rug with a thin cushion under the head the right knee is raised and drawn as close to the chest as possible. Then the leg is extended and the same movements are performed with the left. These movements are repeated five times. Then both knees are raised towards the chest and the pelvis from the floor, placing the hands palms downwards under the hips. These movements are repeated from five to ten times. 2. Lying on the back the feet are drawn up to the buttocks and then the hips are raised from the floor as far as possible bearing the weight on the feet and shoulders. This exercise is repeated ten times. 3. The right leg is raised to the perpendicular keeping the knee as straight as possible, the left leg lying straight on the floor and the hands with the palms downwards being under the hips. This is repeated five times on both sides. Then both legs are raised to the perpendicular an equal number of times. 4. Standing erect with the head and hips held well back the patient inspires deeply and at the same time retracts the lower abdomen as much as possible. Then he relaxes the abdominal wall and expires. He repeats this from five to ten times and while contracting the lower abdomen pushes out the upper; then he reverses the movement, contracting the upper abdomen, causing the wave of contraction to pass downwards over the abdominal wall. 5. Lying in the horizontal position the patient raises the body to the sitting posture, keeping the neck well extended. After from two to three months of this treatment Dr. Seaver advises the substitution for the truss of a flat pad (a convex one would tend to open the inguinal ring). He has used with good results a disc of polished wood 60 millimetres in diameter having a segment removed from the side which lies against Poupart's ligament. This pad is kept in place by a rubber-covered steel spring. When the growth of muscular tissue does not seem sufficiently rapid somewhat vigorous massage of the inguinal region may be performed. The best results are obtained in patients with an inclination for athletics. Dr. Seaver, after a period sufficiently long to test the permanent value of the treatment, has found it successful in 75 per cent. of patients under the age of 25 years. Though as a general rule the treatment appears to be applicable only to those who have not reached physical maturity, occasionally it is successful in older patients. For example, a man, aged 38 years, had worn a truss for 12 years to support a hernia The truss acted satisfactorily but the hernia descended when it was removed. Dr. Seaver recommended operation but the patient would try exercises though he was told that they were useless. The hernia never descended after the treatment was begun and a year later the ring was of normal size But the use of the truss was still advised. Subsequently it was worn only in the afternoon and still later it was worn only during vigorous exercise of which he was very fond. Finally, it was entirely discontinued and although he indulged in heavy gymnastics the hernia did not recur.

[1] THE LANCET, April 2nd, 1904, p. 969.

HYGIENE AND TEMPERANCE AS SCHOOL SUBJECTS.

IT is proposed in a petition signed by a majority of medical practitioners in the United Kingdom that instruction in elementary hygiene, with special reference to the effects of alcohol, should be included among the compulsory subjects of school education. It is pointed out that such instruction is already provided for in the optional code. Attention is also directed to the fact that it forms part of the regular course in army schools. Of Canada as a whole, of Victoria, and of Natal the same is true. In South Australia temperance teaching is systematically carried out. In the United States of America the principles of health and the necessity of temperance are taught, if possible, with even more marked insistence. There can thus be no doubt that the terms of the petition are in accord with the views and the practice of the English-speaking world. Its wording is moderate and judicious and its object, as we have noticed, has already obtained the countenance of the Education Board. Of necessity any project of the kind can only be of limited utility while its promotion is left to the mere choice of individuals. On the other hand, the importance of the subject is generally admitted. Health and sobriety are obviously among our most indispensable national assets. The present relation of education to them can only be justified on the ground that our knowledge of them is instinctive or that it comes to us as a result of our social conditions. But this is not the case. We are therefore left with the alternative that such instruction as is needful for the right understanding of health and temperance must be systematically given. In the public interest we trust that it will be so given.

AN UNUSUAL FORM OF LEAD PARALYSIS

Dr. P. Merklen and Dr. H. Guiard have published in the *Archives de Neurologie* for April an account of a condition resulting from lead poisoning not recorded hitherto and believed by them to be rare The case was one of lead paralysis of very limited localisation, the causation of which was clear, though differential diagnosis was a matter of difficulty. Under prolonged treatment the cure of the patient was complete. The case was one of saturnine paralysis affecting only a small and limited group of muscles of one hand, its rarity being likely to embarrass the diagnosis. Tanquerel des Planches in his classical thesis of 1834 on lead encephalopathy, records a case of isolated paralysis of the fingers and ball of the thumb resulting from lead poisoning, together with a similar involvement of the extensor muscle of the great toe. The case recorded by Dr. Merklen and Dr. Guiard was that of a man aged 35 years, with a good family history except that his mother died at the age of 57 years from rheumatism. There was no personal history of syphilis or of other infectious disease. On June 20th, 1902, the patient suffered from neuralgic pains in the right ilio-lumbar region which disappeared after a little while. Afterwards he had a feeling of "swelling" of the last two fingers of the right hand and of the corresponding portion of the palm. This paræsthesia was accompanied by a general bodily feeling of coldness. Physical examination showed loss of sensibility to touch and pain in the affected area, while the thenar eminence was seen to be atrophied slightly. The first interosseous space also showed a marked flattening (atrophy) of the muscles, which was barely perceptible in the other spaces. He now found it difficult to pick up a coin from the floor. The atrophy and paralysis gradually increased locally. Meanwhile the troubles of sensibility disappeared and only the atrophy remained to disquiet the patient. The grip of the right hand as shown by the dynamometer was one-tenth of the power of that of the left hand. The movements of the thumb were limited and weak. Sensibility to touch and pain was found to be dulled along the radial nerve, especially in its palmar distribution, but sensibility to hot and cold sensations was well preserved. The muscles of the forearm reacted normally to electricity (faradic and galvanic) but the reactions were diminished in the muscles of the hand. There was, however, no reaction of degeneration. Excluding notions of myelopathy and myopathy a peripheral neuritis was diagnosed. On careful inquiry it was found to be due to lead poisoning, as the patient had to handle lead compounds in textile fabrics in the manufacture of which he was engaged. A slight "blue line" was discovered on the gums. He was put under treatment with alkaline iodides, massage, and local applications of electricity. In five weeks considerable improvement had resulted; in seven weeks more there were marked evidences of recovery and the atrophy was visibly passing away; eventually power returned to the right hand, the grip of which was equal to more than half of that of the left hand.

WEIGHTS AND CORRELATIONS OF THE VISCERA.

THE study of the biometric constants of the human body is almost confined to a somewhat limited group of workers who, in addition to an acquaintance with anatomy and pathology, possess a taste for statistics, the analysis of multitudinous data, and arithmetical computation. In a recently issued number of *Biometrika*[1] Mr. M. Greenwood, jun., has published a useful contribution to an important branch of the subject, the full title of his paper being "A First Study of the Weight, Variability, and Correlation of the Human Viscera, with Special Reference to the Healthy and Diseased Heart." His data were obtained from the pathological records of the London Hospital and are distributed for purposes of classification and comparison in 16 tables, most of which are of dimensions exceeding half a page of THE LANCET. He considers the subject under four aspects—namely (1) the average sizes, variabilities, and correlations of the heart, liver, spleen, and kidneys in the general population, diseased and normal, to be found within a London general hospital; (2) the same quantities or ratios for healthy or normal organs only; (3) the influence of age on the biometric constants for the viscera in man; and (4) the influence of certain special diseases. Selecting as illustrative examples only the figures relative to the heart and liver (of course taken jointly or in combination) we observe that for the general hospital population the mean weights of the heart and liver are given respectively as 13·53 and 63·01 ounces, the correlation of heart and liver being 0·1931 ± 0·0175 This weight of the heart is obviously higher than that usually given in anatomical text-books and in this place Mr. Greenwood remarks that in making the records there has been "some special reason for measuring livers in the case of very large hearts." For healthy organs the mean weights of the heart and liver are given respectively as 11·04 and 60·44 ounces, the correlation of heart and liver being 0·2780 ± 0·0329. In cases of pneumonia the mean weight of the heart is above that of the healthy heart but is slightly below that of the general hospital population heart. On the other hand, valvular disease and aortic aneurysm send up the weights of both the heart and the spleen not only vastly above their healthy values but markedly above the values for the general hospital population.

TRAUMATIC HÆMATOPERICARDIUM.

IN the *Boston Medical and Surgical Journal* of March 3rd Dr. J. L. Morse has reported an interesting case of hæmatopericardium due to an unusual cause. A girl, aged two and a half years, while looking out of a window fell forwards on a needle which was on the window-sill. The needle entered the chest near the right edge of the sternum and broke off. An incision was made over the point of entrance but nothing was found. She remained apparently well for two weeks and then her appetite failed, respiration became difficult, and she complained of pain in the side. On July 10th, a month after the accident, she came under Dr. Morse's care. The cardiac impulse could not be felt and the heart sounds were faint. Cardiac dulness extended on the right to the parasternal line and upwards to the junction of the manubrium and gladiolus and to the left first intercostal space. Dulness extended over the whole of the left chest in front and thence backwards as far as the posterior axillary line. Over this area respiration was diminished. The temperature was 100 6° F., the pulse was 130, and the respirations were 50. On the 11th radioscopy showed that the cardiac shadow extended up to the first rib on both sides, to the right two and a half centimetres from the middle line, and to the left three centimetres from the middle line. No needle was seen. Thus the physical signs were not characteristic of fluid in the pericardium but the radioscopic examination was. An aspirating needle was introduced into the right fifth intercostal space at the edge of the sternum and bloody fluid escaped under considerable pressure. As serous or purulent fluid was expected it was thought at first that the heart had been tapped and the needle was at once withdrawn. But it was soon evident that the heart had not been wounded, for its action was unaffected. The needle was then introduced into the sixth left space, nine and a half centimetres from the middle line. Dark bloody fluid issued under great pressure. More than 100 cubic centimetres escaped; then 400 cubic centimetres more were withdrawn by aspiration. The heart sounds became louder and a friction sound was heard. The child was much relieved by the operation. On the 13th a feeble cardiac impulse was visible. The cardiac dulness extended upwards to the upper border of the third rib, to the right two and a half centimetres from the middle line, and to the left seven and a half centimetres in the sixth space. The front of the left chest was still slightly dull. Radioscopy showed that the cardiac shadow extended upwards to the lower border of the second rib and to the right about one and a quarter centimetres from the middle line in the fourth and fifth spaces. It is difficult to explain why the cardiac area appeared to be normal on radioscopy but larger on physical examination. The child was discharged well on July 15th. Just before her discharge radiographs were taken and showed that half of the needle still remained behind the sternum. Operation was advised but declined. Dr. Morse explains the fact that an interval elapsed between the accident and the onset of symptoms by supposing that the needle did not at first reach the pericardium but later worked its way to it. The fact that the needle did not scratch the pericardium and cause fresh bleeding after the removal of the fluid was no doubt due to its becoming encapsuled.

A SESSIONAL meeting of the Sanitary Institute will be held at the Parkes Museum, Margaret-street, London, W., on Saturday, April 30th, at 11.30 A.M., when a discussion will take place on Food and Meat Inspection. The discussion will be opened by Colonel J. Lane Notter, R.A.M.C., and Mr. W. Hunting, F.R.C.V.S. General discussion is invited. The chair will be taken by Mr. Charles Game, chairman of the Cattle Markets Committee, Corporation of London. The meeting will adjourn for luncheon at 1.30 P.M. and at 3 P.M. a visit will be paid to the Metropolitan Cattle Market, York-road, Islington, conducted by Mr. J. King, M.R.C.V.S. Tickets for admission of visitors may be had on application to the secretary, Mr. E. White Wallis, 72, Margaret-street, London, W. The institute dinner will be held in the Whitehall Rooms of the Hôtel Métropole, London, S.W., on Monday, May 2nd. Dr. Robert Farquharson, LL.D., M.P., Vice-President of the institute, will take the chair and will be supported by the Right Hon. Sir John Ure Primrose, Sir William Church, Bart., Sir R. Douglas Powell, Bart., Sir R. M. Hensley, Sir Henry Norbury, Sir William Taylor, Sir William White, Mr. J. Tweedy, Dr. J. Groves, the Mayors of Hampstead and St. Marylebone, and the council of the institute.

WE have received the first of the scientific reports of the investigations of the Cancer Research Fund which deals with the zoological distribution, the limitations in the transmissibility, and the comparative histological and cytological characters of malignant new growths. Dr. E. F. Bashford's and Dr. J. A. Murray's paper read before the Royal Society on Jan. 21st and published in THE LANCET of Feb. 13th, 1904 (p. 413), contains the gist of this report which records fully the attempt made to investigate cancer from a standpoint in keeping with the extent to which it pervades the animal kingdom. The investigations have been conducted by Dr. Bashford, the general superintendent and director of the Central Laboratory, whose work has been, to use Dr. Bashford's words, "in every sense carried on conjointly with Dr. J. A. Murray, who shares with me the responsibility for the observations and the deductions based upon them."

AT a meeting of the Metropolitan Asylums Board held on April 16th a memorial signed by some 13 medical superintendents was considered protesting against a recent decision of the hospitals committee that the supply of coal, gas, or electricity should be limited. A somewhat heated discussion followed but eventually a motion, proposed by Mr. W. H. Ecroyd, seconded by Mr. G. S. Elliott, and warmly supported by Mr. W. Crooks, M.P., was carried to the effect that the memorial should be remitted to the General Purposes Committee for consideration and report.

His Majesty the King, having been invited by the secretary of the South London Schools' Athletic Association to be present at the Annual Athletic Festival at Herne Hill on June 22nd, has replied through Captain Ponsonby that, while regretting, owing to his numerous engagements at that time, he will not be able to be present, he regards with satisfaction the importance which is now attached to the physical development of children and that he takes great interest in all institutions which have for their object the improvement of the physique of the young.

VIVISECTION AND MILK-SUPPLY.

WITH the approach of warmer weather the necessity of increasing the severity of sanitary precautions annually recurs. Of course, it is on infant life that any defect in sanitation makes itself most felt. As infants depend on milk, and very often it is not the mother's but cow's milk, there is, no doubt, a marked connexion existing between the quantity and quality of the milk-supply and the prevalence of infantile mortality. So convinced are many of our sanitary authorities on this point that they have induced their town councils to obtain special legal powers more effectively to control the milk-supply. This is notably the case with the corporations of the cities of Manchester and Glasgow. The remarkable series of experiments made by Professor S. Delépine provided ample scientific evidence to prove how necessary it is to supervise minutely milk supply and distribution. After examining milk during many years, Professor Delépine concluded that to detect a small number of bacilli within a practical length of time the inoculation method was much more trustworthy than the mere use of the microscope. The tubercle bacillus was only detected with the microscope in one half of the samples of milk which were proved by inoculation to be tuberculous At the Congress on Tuberculosis held in London in 1901, Dr. James Niven, medical officer of health of Manchester, related that in 1899 samples of mixed milk from 401 farms supplying the city of Manchester were taken and on examination 47, or 11·7 per cent., proved to be tuberculous. Of 108 samples of milk taken at the railway stations 18·5 per cent. were tuberculous, consequently, and if this cannot be stopped, it would apparently mean that at least once in ten times the Manchester purchaser of milk is served with milk containing pathogenic germs of tuberculosis. It must be confessed that, in any case at first sight, these figures seem to defeat the purpose for which they are brought forward. If in every ten cups of tea we get one dose of the tubercle bacilli it does not seem as if these germs were very mischievous, otherwise no one would escape. It is, however, in regard to infants that the greatest danger arises and then also it is not merely a matter of infection but of the amount of infection. This question of the amount applies to infants, for with them milk is the sole or the principal food given and excessive infantile mortality is still very prevalent where it is difficult to obtain pure milk.

The difficulties of dealing with tuberculous cows are very great. It has been clearly shown that a tuberculous cow may at first appear perfectly healthy, that no mere manipulation of the udders discloses any suspicious symptom. Then, again, the contaminated milk, if only examined by the microscope, will not always appear to be infected. Nevertheless when the bacilli are not numerous enough to be detected by the microscope they will be very perceptible in the deep inguinal glands of the guinea-pig 15 days after inoculation. Later the presence of tubercle may be detected by the veterinary surgeon who examines the udders of the cow but there are periods when the presence of the disease can only be detected by experiments on living animals. How the antivivisectionists mean to meet this difficulty it is hard to say. Mr. J. S. Lloyd, late veterinary surgeon to the city of Manchester, calculated that out of a grand total of 9576 cows, the milk of which was tested for tuberculosis, there was 0·54 per cent. of the cows with tuberculous udders. According to the agricultural returns for 1900 the number of cows in milk in England was 1,899,623. If the proportion resulting from the very extensive examinations made by the Manchester authorities is applied to England then there should have been 10,257 cows with tuberculous udders. Applying thes ame calculation to Great Britain we have 2,620,901 cows in all of which 14,152 had tuberculous udders. Those persons who are so very much concerned about the welfare of animals might consider the condition of these 14 000 to 15,000 tuberculous cows that in all probability are now in our midst. It is, perhaps, of no use to ask the antivivisectionist to display some concern as to the fate of the infants who drink the milk derived from these cows and to consider that this milk being mixed with other milk we have, as a result, the contamination of about 10 per cent. of the total milk-supply, even though only about one cow in 200 has tuberculous udders. But these tuberculous cows are either prematurely slaughtered or live to suffer from the disease which they have contracted. It might be worth while to attempt to do something to save the cows from the danger of contamination. Setting human beings aside as unworthy of consideration where animal life is concerned the question might be put to the antivivisectionist whether it is not worth while to sacrifice a few guinea-pigs for the sake of saving a much larger number of cows. The fact that this would save a still greater number of human beings will, we trust, not mitigate against any effort being made on behalf of the cows.

The great points are the immediate detection of tuberculosis and the isolation of the affected cow before it has time to contaminate other cows. For this purpose some towns have acquired powers that are more extensive than exist elsewhere. Within the boundaries of the town itself the matter depends on the sanitary authorities but the greater part of the milk of large towns comes from beyond the boundaries. The cowsheds, &c., within the town may, of course, be inspected but special powers have to be confirmed by Act of Parliament so as to extend this right of inspection to farms situated in the country. Even when this is granted an order must first be obtained from a justice having jurisdiction in the place where the sample is to be taken. Should it then be proved that the cow in question is tuberculous the owner can be forced to isolate the animal and can be fined to the extent of £5 if he does not do so.

The farms, however, are scattered over so many counties that it is almost impossible to control them properly. When samples are taken at the station on the arrival of the milk train the farmer somehow hears of it and by the time a magistrate's order has been obtained to inspect his farm the cow or cows that contaminated his milk have been slaughtered or sold or sent elsewhere. But even if the cow remains and its diseased condition is demonstrated the farmer can only be compelled to isolate the cow and there is no one to watch in order to see that such isolation is constant and effective. But, what is worse, the farmer is free to sell the cow and it may be taken to some other locality where the fact that it is diseased will be more successfully concealed and there will be no one to prevent the sale of its milk. The last published annual report of the medical officer of health of the city of Manchester shows how the system works, for this is one of the towns which possess special powers in regard to milk-supply. It is stated that during the year 1902. though 5649 inspections of cows were made in the Manchester cowsheds, not a single cow was found to be suffering from tuberculosis of the udder. This shows what inspection can do and it is more difficult to keep cows healthy in town than in the country. Yet how different was the result when dealing with the milk that [illegible] of the Manchester Cor- [illegible] efficient control cannot [illegible] amples of milk coming from 345 farmers were taken at the Manchester railway stations. Of these farmers, 196 reside in Cheshire and 25 of them, or 12·72 per cent., sent tuberculous milk. 104 live in Derbyshire and nine of them—that is, 8 65 per cent.—sent tuberculous milk. From Staffordshire 4 01 per cent. and from Lancashire 8 31 per cent. of the farmers sent tuberculous milk. On the 345 farms there were 6210 cows and in following up the evidence of the presence of tuberculosis at 36 farms 1236 cows were examined. 31 cows were found with tuberculosis of the udder and 15 were forthwith slaughtered, but 15 disappeared, were sold, and no one knows what further mischief they may have done. As 36 samples from 345 farms taken during 1902 contained tubercle bacilli this is equal to a percentage of 10·43 There is surely something very striking in this percentage of contamination, particularly when compared with the fact that the cows in the town cowsheds were inspected 5649 times and not a single case of tuberculous infection of milk was found.

Such a comparison is a clear proof that great improvements are possible where efficient control can be established. But a long time must elapse before the numerous small farms scattered over rural districts can be brought up to the level of modern sanitary requirements. In the meantime the presence of infection has to be demonstrated positively before the legal power to act can be obtained. But the antivivisectionist would render such a demonstration impossible. The report, after giving the above figures, goes on to say :—

> There is no doubt that as time goes on the detection of tuberculosis of the udder becomes increasingly difficult. The class of cases met with at one time are now almost never seen. I refer to the well-marked cases in which there was no difficulty in diagnosis. In by far the greater [illegible] ow found a reliable diagnosis is impossible [illegible] examination. The cases found being so sli [illegible] naking an inspection of a herd of dairy cows to make one's observations as complete as possible, always remembering that you can only form a suspicion, and that it is for the bacteriologist to say whether the suspicion is well founded or not. In several cases I have taken samples from cows whose udders have shown no sign of disease, my suspicions being perhaps aroused by some other symptom or combination of symptoms external to the udder, and the milk has been found to be tuberculous.

One of the worst cases occurring during the year related to five samples of milk taken at a railway station from separate cans that all came from a large dairy in Shropshire. Professor Delépine produced tuberculosis with three of these samples and the animals experimented upon with the two other samples died from septic infection. With such evidence to go upon it was possible to obtain magistrates' orders, and ultimately, arising out of this one case alone, 75 farms, 181 cowsheds, and 2420 cows were visited. Very little of the milk from these cows had been sent to Manchester, it being for the most part despatched to London. Many of the cowsheds were in a filthy and very insanitary condition and contagious abortion prevailed. In one farm, out of 47 cows 34 aborted. All these evils would probably have remained undiscovered but for Professor Delépine's experiments on animals. Again, it may be asked whether it was not worth while to sacrifice a few guinea-pigs so as to improve greatly the condition of the 2420 cows concerned in the experiments made with the five samples of milk. Nothing shall be said as to the human beings who in Manchester and London consumed the milk derived from all these cows and who were saved from further contamination by the sacrifice of a few guinea-pigs. The antivivisectionist does not admit that animal life should be sacrificed to save human life. In these circumstances he cannot logically be a meat-eater but even vegetarians recognise that it is necessary to have milk. Some might go so far as to allow that it is necessary to have leather. We are not aware that the antivivisectionist has ceased to wear boots or that he objects to leather harness for his horses. Then there are many industries that employ large bones, so that when the antivivisectionist vegetarians have triumphed along the whole line the existence of cows and the drawing of their milk may still be tolerated. How is the health of these cows going to be preserved? More than 2000 cows connected with one single Shropshire dairy have every reason to be grateful to Professor Delépine for his experiments on guinea-pigs. But the antivivisectionists would have prevented these experiments and therefore it seems that instead of reducing the amount of suffering which animals endure they would, on the contrary, greatly increase the prevalence of disease among them. It is obviously a mistake to imagine that vivisection is only useful to human beings. When applied for the control of milk-supply it becomes the means of saving from disease not human beings only but also a vast number of cattle. The discovery of a case of tuberculosis of the udder means official pressure being brought to bear so that the sanitation of cowsheds, &c., shall be improved. It has been stated that there are more than 2,500,000 milk-giving cows in Great Britain. Is this not a total of animal life worth considering from the humanitarian point of view? The sanitary improvements which the control over milk has shown to be necessary will also affect beneficially the cows that are not milk-givers, and the bulls, the bullocks, and the calves as well. The argument might be carried much further, as it applies to many other animals. What, however, has been said in regard to milk will doubtless suffice. Here the practice of vivisection has proved of benefit to the cows. Of course, it is obvious that what is useful—for instance, good sanitation and antiseptic precautions—to the medical practitioner when treating human beings as his patients is also useful to the veterinary surgeon when treating animals as his patients. Animal life, especially in the case of animals of higher organic development such as horses, dogs, cattle, sheep, and others, has as much to gain from the knowledge which is derived from the practice of vivisection as has the human family itself.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A quarterly meeting of the Council was held on April 10th, Mr. John Tweedy, the President, being in the chair.

In accordance with the recommendation of the Jacksonian Committee the Jacksonian Prize was awarded to the author of the dissertation on the Various Forms of Conjunctivitis, their Pathology and Treatment, bearing the motto "Fiat lux." The President opened the envelope bearing this motto and declared Mr. M. Stephen Mayou, F.R.C.S., to be the author of the successful essay and it was resolved that Mr. Mayou should be requested to attend the next meeting of the Council to receive the Jacksonian Prize. It was resolved that the subject for the Jacksonian Prize for the year 1905 should be the Pathology and Treatment of Deformities of the Long Bones due to Disease occurring during and after Adolescence.

In accordance with the recommendation of the Triennial Prize Committee the Collegial Triennial Prize was awarded to Mr. T. R H. Bucknall, F.R.C.S., for his dissertation on the Pathological Conditions arising from Imperfect Closure of the Visceral Clefts. It was resolved that Mr. Bucknall should be requested to attend the next meeting of the Council to receive the Collegial Triennial Prize and that he be asked whether he would prefer the John Hunter Medal executed in gold to the value of £50 or the said medal executed in bronze with an honorarium of £50 It was resolved that the subject for the next triennial prize should be the Effects of Nerve Lesions on Growth and Development.

A report was received from the Laboratories Committee and was adopted. Among other matters it contained the statement that Dr. T. G. Brodie has collected one volume of papers relating to researches carried out in the laboratories during the early period of his tenure of office and that he hopes shortly to be in a position to issue a second volume containing the papers published during the later period. It has not been found possible to compile a volume of papers published during Professor G. Sims Woodhead's term of office as director and therefore the secretary has been requested to print an index of all papers issued from the laboratories, with references, where known, to the publications in which they appeared.

A report was received from the Conjoint Committee and was adopted. It dealt with the course of study during the first year of the curriculum and the scope of the first examination. It submitted recommendations and syllabuses drawn up after consultation with the examiners and teachers on the various subjects.

Mr. W. H. A. Jacobson was elected a member of the Court of Examiners in the vacancy occasioned by the resignation of Mr. Henry Morris.

The Council proceeded to the election to the Fellowship of a Member of 20 years' standing and Mr. Edward Ward, professor of surgery in the Yorkshire College, Leeds, was elected.

A letter was read from the Irish branch of the British Dental Association calling attention to the judgment in "O'Duffey v. Jaffe, Surgeon Dentists, Ltd.," and asking the College to instruct its representative on the General Medical Council to support action on the part of that body towards petitioning the Privy Council to initiate legislation necessary to obviate the evils disclosed. Mr Henry Morris, the representative of the College, was requested to take such steps as seemed to him desirable in order to assist this matter.

The President reported that Mr. A. Pearce Gould's period of office on the Court of Examiners would shortly expire and that the vacancy thus occasioned would be filled at the next meeting of the Council on May 12th, together with the vacancy caused by the resignation of Mr. Henry Morris, Mr. Gould being a candidate for re-election. Applications for the examinership must be sent in on or before May 4th.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 22, 1826.

"THE Chinese, whom I venture to pronounce the most unique, and the most original people at this day on the face of the earth, look at medicine in two points of view, a favourable one, and an unfavourable.

The sincere, diligent, candid, and benevolent practitioner who toils for the health of his neighbours and fellow-countrymen, they regard as holding a place equal in importance to that of a virtuous minister of a powerful monarch, who is a blessing to the empire. On the other hand he who has no higher motive than his own emolument, and who, from his ignorance or his foolhardiness, as often kills as cures, they regard with sovereign contempt, and feel ashamed that such men should be called by the same name as the sincere votaries of the healing art, which, by a very appropriate and honourable distinction, they call Jinshuk, 'the benevolent art.' The ideas I have thus put into English, are taken from the preface of a work in forty volumes, compiled by the united efforts of about a hundred persons connected with the Imperial College of Physicians at Pekin during the reign of th- [illegible] monarch, known by the name, [illegible] which being interpreted, mean [illegible] which is the latest national work in China on the subject to which this paper has a reference, was published about the year A.D. 1740.

There is an individual and private work in eleven volumes, printed not more than fourteen years ago, entitled E-Shoo-Hwuy-Tsan, '*A Comparative Compendium of Medical Books.*' This is the latest publication which has any pretensions to particular notice that I have seen.

The imperial work above referred to, is entitled E-tsung kin-këen, '*A Golden Mirror of the most approved Medical Practice.*' All books in China referring to medicine, that could be procured by purchase or by loan, were collected, and traditional popular MSS. were sought by the order of government. In four years it was completed. In this work it is maintained, that in the remote ages of antiquity, medicine and the affinities and correspondencies in nature were better understood than at any subsequent period.

Chinese writers attribute the ascertainment of the properties of herbs to Yente, the illustrious monarch, an antediluvian personage in their annals, placed about 3000 years before our era. This illustrious king, Yente, is otherwise called Shinmuy, which appellation means 'Divine Husbandman.' About the same time lived another king, Hëen-yuen, and a statesman named Ke-pih, who, with the monarch just now named, formed, by their personal efforts, a sort of royal society for physical and medical research in China, and in allusion to them, medicine is sometimes called '*the art of Ke heen.*' To Ke-pih the origin of Tsze-chih, i.e., '*impuncture,*' is attributed. There are two fragments yet extant attributed to Ke-pih, and which (according to the imperial editors and other writers) are the most ancient notices in China concerning the cause and cure of diseases.

Both these medical fragments are given in the work published fourteen years ago by a private hand, to which I referred in the beginning of this paper. They are considered more ancient than the classical books collected and edited by Confucius; but how their authenticity and genuineness are traced, I know not.

The Shoo-king compiled by Confucius, mentions Woo-hëen as skilled in the cure of diseases about 3000 years ago. The next names of eminence in this department are Tsang-kung and his pupil Peen-tsoo, otherwise called (Looe) Doctor of Loo, who lived about 2100 years ago. Shun-yue, a doctor of some note, lived about this time.

In the fourth century Wang shuh-ho was chiefly famous for his work on the pulse, an epitome of which is given in Du Halde's China.

In the sixth century Chin-kwei lived, who is said to have cut into the abdomen, removed diseased viscera, stitched up the part again, and healed the patient in a month's time. He gave an opiate to the patient, which rendered him insensible, before he began the operation. The opiate is called Ma-fuh-san, which seems to express that it was in the form of a powder.

There was one man of eminence called Heuyin-sung, who rather undervalued the doctrine of the pulse, and said he could do without it.

The above-mentioned are a few of the desultory names of eminence connected with China; there are four persons still more eminent as writers, and who are well known by the epithet Sze-ta-kea, 'the four great masters,' or leaders of separate schools, and authors of distinct systems. From the first of them to the last embraced a period of twelve centuries.

The first is King-chung-chang. He lived during the How-han, A.D. 220, and was a native of Nan-yang.

The next is Lew-chow-chin. He lived under the Sung dynasty, A.D. 1200.

The third is Le-tung-hwan, who lived under the first Tartar dynasty, A.D. 1300; and the last is

Choo-tan-ke, a native of Che-keang province, who lived during the late China dynasty, Miny, A D 1500.

The first name is considered 'The father of Physic:' he left numerous writings, which are still much read."[1]

MEDICINE AND THE LAW.

Unqualified Practice under the Cover of a Limited Company.

AT Bolton borough police-court an unqualified person was recently convicted under Section 3 of the Dentists Act, 1878, of having unlawfully taken and used the title of dentist, implying that he was registered under the Act. Evidence was given that outside the premises where the unqualified practice took place appeared the inscription, "Reynolds, dentist," and that in a room fitted up as a dental surgery the defendant, whose name was Richard Willoughby Reynolds, was asked if he was "Mr. Reynolds, dentist," and answered that he was "one of them." In cross-examination it was denied that words were to be seen indicating that the business was carried on by a limited liability company. Evidence was, however, called by the defence to prove the registration of a company under the Companies Acts with the title, "Reynolds and Sons, Dentists, Limited," and an agreement was put in made by the "company" on the one side and the defendant on the other. It was also alleged that the full title of the company was displayed. It was not suggested that the defendant or anyone holding any shares in, or connected with, the company was qualified. The advocate for the defence contended that the defendant was merely the servant of a company, that the practice of dentistry by an unqualified person was not illegal, and that the magistrates must be satisfied that Reynolds had held himself out to be a person on the Dental Register. The magistrates found as a fact that Reynolds had committed the offence with which he was charged, and being further pressed for a finding as to his relations with the company found that he was acting as principal, basing their view upon his own admissions. They inflicted a fine of £10 with costs and declined to state a case for the consideration of the High Court. The position which arises when an unqualified person registers a company with a view to practising medicine or dentistry under a name which obviously implies qualification and registration but to which the word "limited" is appended was fully discussed in THE LANCET of March 19th, p 814. It was then pointed out that the company cannot be summoned as such and convicted of using a name or title implying registration because a corporation cannot in any case be placed upon the medical or dental register. On the other hand, an individual who practises under cover of a company can be convicted of the offence if the bench is satisfied that as a fact he committed it. The question, of course, is what the titles used would imply to the persons to attract whom they are displayed.

The Supply of Artificial Teeth by Unregistered Persons.

A somewhat analogous case came before the Divisional Court on April 18th when the Lord Chief Justice and Mr. Justice Wills upheld the decision of a county court judge in a case in which unqualified persons trading as a limited company sued for dental work. The claim was in respect of filling teeth and of a partial set of artificial teeth supplied. The county court judge had allowed the claim so far as it was for making the set of teeth and not for fitting them or for filling teeth, and the appeal was brought by the defendant against this decision. The Dentists Act, 1878, provides that "a person shall not be entitled to recover any fee or charge for the performance of any dental operation or for any dental attendance or advice unless he is registered under this Act or is a registered medical practitioner." In dismissing the appeal both judges expressed reluctance to adopt the construction of the Dentists Act which the terms of the section quoted rendered necessary, laying stress on the importance to the public that patients should be supplied with properly constructed teeth, supplied and fitted by qualified dentists. The Lord Chief Justice, however, was of opinion that "dental operation" must refer to an operation performed upon the mouth of the patient and he also called attention to the wording of the corresponding section of the Medical Act in which the words "any medicine supplied" are inserted. The Dentists Act contains no corresponding words applicable to artificial teeth. His lordship also pointed out that such teeth were no new invention but were well known as work within the scope of the dentist's profession when the Act was passed. The matter is therefore one for future legislation if any change is to be brought about and the decision settles a point which has long been considered doubtful.

---

[1] Excerpt from Review of *Medical and Surgical Cases* by Edward Sutliffe, Queen-street, 8vo, pp 464. Vol. II. London, 1825. Printed [illegible]

The Regulation of Underground Bakehouses.

At Bradford police-court on April 16th the stipendiary magistrate, Mr. Charles Skidmore, gave his decision with regard to a summons taken out by the Bradford corporation under Section 161 of the Factory and Workshop Act, 1901, against a firm of bakers using an underground bakehouse. It had been submitted on behalf of the defence at the hearing of the summons that the bakehouse having been in existence before the passing of the Act was exempt from its provisions. The magistrate having referred to the authorities upon the subject upheld this contention and dismissed the summons. A case for the consideration of the High Court was applied for.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9230 births and 5142 deaths were registered during the week ending April 16th. The annual rate of mortality in these towns, which had been 18·7, 18 7, and 18 3 per 1000 in the three preceding weeks, further declined last week to 17·6 per 1000. In London the death-rate was 16·7 per 1000, while it averaged 17·9 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 8·2 in Reading, 9 7 in Southampton, 9·8 in Tynemouth, 10·3 in Walthamstow, 10·6 in Hanley, 10·9 in Hornsey, 11·0 in Hastings, and 11·5 in York; while the highest rates 22·1 in Birmingham, 22·3 in Smethwick, 22·9 Newcastle-on-Tyne, 23·2 in Wigan, 23·9 in Norwich, 24·0 in Great Yarmouth, 24 7 in Aston Manor, and 25 2 in Halifax. The 5142 deaths in these towns last week included 530 which were referred to the principal infectious diseases, against 532, 640, and 583 in the three preceding weeks; of these 530 deaths 216 resulted from whooping-cough, 191 from measles, 41 from diphtheria, 35 from diarrhœa, 21 from scarlet fever, 20 from "fever" (principally enteric), and six from small-pox. No death from any of these diseases were registered last week in Hastings, Bournemouth, Southampton, Northampton, Great Yarmouth, Burton-on-Trent, Smethwick, Grimsby, Barrow-in-Furness, York, West Hartlepool, South Shields, or Newport (Mon.); among the other towns the highest death-rates from the principal infectious diseases were recorded in Norwich, Wolverhampton, Handsworth (Staffs.), Birmingham, Aston Manor, Bootle, St. Helens, Salford, and Gateshead. The greatest proportional mortality from measles occurred in Tottenham, Norwich, Aston Manor, St. Helens, Salford, Burnley, Leeds, nd Hull; and from whooping-cough in Hornsey, Wolver- mpton, Walsall, Handsworth (Staffs.), Birmingham, Aston nor, Wallasey, Bootle, and Newcastle. None of the other ipal infectious diseases showed a marked excess in the large towns. Of the six fatal cases of small-pox registered in these towns last week three belonged to Gateshead and one each to Bristol, Leicester, and Tynemouth. The number of small-pox cases remaining under treatment in the Metropolitan Asylums hospitals, which had been 110, 126, and 134 at the end of the three preceding weeks, had further risen to 144 at the end of last week; 37 new cases were admitted during the week, against 54, 42, and 25 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday last, April 16th, was 1523, against 1585, 1570, and 1505 on the three preceding Saturdays; 172 new cases were admitted during the week, against 145, 153, and 141 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 383, 370, and 333 in the three preceding weeks, further declined last week to 295, but were 31 in excess of the number in the corresponding period of last year. The causes of 54, or 1·1 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Salford, Bradford, Leeds, Newcastle-on-Tyne, and in 42 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Sheffield, Hull, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 22·3, 20·6, and 20·3 per 1000 in the three preceding weeks, further rose last week to 20·9 per 1000, but was 3·3 per 1000 in excess of the mean rate during the same period in the large English towns. The rates in the eight S ranged from 13·8 in Perth and 15 0 in Greenock, to Paisley, and 26·5 in Dundee. The 690 deaths towns included 21 which were referred to meas whooping-cough, 15 to diarrhœa, four to "f to small-pox, one to scarlet fever, and one In all, 65 deaths resulted from these diseases last week, against 86, 72 preceding weeks. These 65 death rate of 2·0 per 1000, which the mean rate last week from 76 large English towns. T easles, which had been 22, 23, and the three preceding weeks, rose again last week to 21, of which 12 occurred in Glasgow, five in Greenock, and three in Dundee. The deaths from whooping-cough, which had been 29, 23, and 19 in the three preceding weeks, rose again to 20 last week and included seven in Glasgow, five in Edinburgh, four in Dundee, and three in Paisley. The fatal cases of diarrhœa, which had been 15, nine, and seven in the three preceding weeks, increased again last week to 15, of which seven were registered in Glasgow, three in Edinburgh, and two in Dundee. The deaths referred to different forms of "fever," which had been four, four, and three in the three preceding weeks, increased again to four last week. The fatal cases of small-pox, which had been seven, five, and seven in the three preceding weeks, declined again last week to three and were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 165, 157, and 138 in the three preceding weeks, rose again last week to 152, and were 43 in excess of the number in the corresponding period of last year. The causes of 25, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 30·4, 28·5, and 29 7 per 1000 in the three preceding weeks, declined again to 24·4 per 1000 during the week ending April 16th. During the past four weeks the death-rate has averaged 28 3 per 1000, the rates during the same period being 18 1 in London and 19 6 in Edinburgh. The 177 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 42 from the number in the preceding week and included 17 which were referred to the principal infectious diseases, against 14, 20, and 19 in the three preceding weeks; of these, 11 resulted from whooping-cough, four from measles, one from diphtheria, and one from "fever," but not any from small-pox, from scarlet fever, or from diarrhœa. These 17 deaths were equal to an annual rate of 2·3 per 1000, the death rates last week from the principal infectious diseases being 1·9 in London and 1·4 in Edinburgh. The fatal cases of whooping cough, which had been five, 11, and eight in the three preceding weeks, rose again last week to eight. The four deaths from measles corresponded with the number in each of the two preceding weeks. The 177 deaths in Dublin last week included 38 of children under one year of age and 42 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week. Four inquest cases and five deaths from violence were registered, and 55, or nearly a third, of the deaths occurred in public institutions. The causes of seven, or over 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Hamilton Meikle has been placed on the Retired List of his rank (dated April 6th, 1904).

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet:—Thomas Tendron Jeans, John Hunter Pead, and Hugh Somerville Burniston (dated May 16th, 1902); Harold Paget Jones and Albert Otto Bobardt (dated Nov. 14th, 1902); Sidney Thomas Reid (dated May 15th, 1903); and Charles Henry James Robinson and Harold Huskinson (dated Nov. 12th, 1903.)

ROYAL ARMY MEDICAL CORPS.

Captain St. J. B. Killery, attached to the Scots Guards, is nominated for appointment to the Royal Horse Guards. Captain J. M. Buist is appointed Clinical Pathologist to the Royal Herbert Hospital, Woolwich. Lieutenant-Colonel G. A. Hughes, D S.O., to be Colonel, vice R. de la C. Corbett, D S.O, deceased (dated March 25th, 1904); Lieutenant J. H. R. Winder to be Captain (dated Feb. 27th, 1904). Lieutenant-Colonel R. C. K. Laffan retires on retired pay (dated April 16th, 1904). Captain G. Dansey-Browning is seconded for service with the Egyptian Army (dated March 31st, 1904).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Lieutenant R Le G. Worsley resigns his commission (dated April 16th, 1904).

CHANNEL ISLANDS MILITIA.

Royal Jersey Light Infantry: 2nd or East Battalion: Surgeon-Captain F. N. Gaudin to be Surgeon-Major (dated March 19th, 1904). 3rd or South Battalion: Medical Corps Section: Surgeon-Major P. B. Bentlif from Royal Jersey Artillery, to be Surgeon-Major, with seniority from July 27th, 1901 (dated March 19th, 1904); Surgeon-Captain A. C. Stamberg, from 2nd or East Battalion Royal Jersey Light Infantry, to be Surgeon-Captain, with seniority from Feb. 21st, 1903 (dated March 19th, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Devonshire: Surgeon-M [illegible] Colonel ([illegible] Joseph O' [illegible] 1904).

Royal Engineers (Volunteers): 1st Sussex: Sugeon-Lieutenant E. S. Cardell resigns his commission (dated April 16th, 1904).

Rifle: 1st Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant L. J. Blandford to be Surgeon-Captain (dated April 16th, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Major T. W. Gibbard is permitted to complete three years as Adjutant of London Companies, R A.M.C. (Volunteers).

The London Companies: Surgeon-Major V. Matthews to be Surgeon-Lieutenant-Colonel and to command under paragraph 55A Volunteer Regulations (dated April 9th, 1904).

THE LATE STAFF SURGEON W. ROGERS, R N.: A MERITORIOUS ACT.

The late Staff Surgeon William Rogers, R.N., whose death was recorded in THE LANCET of April 16 (p, 1080), received his promotion to staff surgeon in 1845 for an act of devotion to duty which is well worthy of record. During 1845 H.M. steamer *Eclair* sailed from Sierra Leone with the crew suffering from yellow fever. At Buena Vista, one of the Cape Verde Islands, the whole of the ship's company were landed and the ship was thoroughly cleansed and fumigated. 31 of the officers and men died on the island in three weeks and it was then decided that the ship should return to England. Before leaving Mr. McClure, a naval surgeon, and seven seamen volunteered their services on the *Eclair* and Mr. McClure fell a victim to the fever. Before reaching Madeira the captain died and at that port Mr. Bernard, another naval surgeon, and two seamen volunteered their services. During the voyage from Buena Vista to England the ship lost at the rate of one man a day. On her arrival in England Staff Surgeon Rogers, then Surgeon, volunteered to board her and in attending to her stricken crew he contracted the disease himself. For a time he was dangerously ill but eventually recovered and received the promotion which he so well deserved. The *Eclair* was renamed the *Fair Rosamond* but a second outbreak of fever occurred on her and she was broken up.

A SOLDIERS' AND SAILORS' TEMPERANCE CLUB AT TOULON.

The *Revue Scientifique* of April 9th states that more than a year ago the Temperance Society of Toulon wrote to the majority of the officers in command of the Mediterranean squadron as well as to various commanding officers of the port inquiring what number of soldiers and sailors would be likely to make use of a temperance club. The result has been that upwards of 2000 men have declared themselves to be in favour of the formation of such a club provided that religion and politics are excluded. The institution will be an addition to the number of the "Foyers du Soldat" which already exist at Vincennes, Valence, and Saint-Etienne. Being situated at a naval station its full title will be "Foyer du Marin et du Soldat." The premises will comprise a large reading room provided with books, periodicals, and writing materials; a large recreation room with three billiard tables, a piano, and of course such games as chess, draughts, and dominoes; a store room for bags and other property belonging to the men; and a place for playing bowls, skittles, and similar outdoor games.

THE SENIOR MEDICAL OFFICER OF THE "PETROPAVLOVSK."

Andrew Nikolaevitch Volkovitch, who was the senior medical officer on board the battleship *Petropavlovsk* and who went down with his ship, came of a good family of the government of Smolensk. He was born in Minsk in 1870. He finished his course in the Military Medical Academy in 1894 and whilst still a student in 1892 he obtained leave to go into the Viatska government to assist to combat the then raging typhus fever and cholera. Amongst his numerous services there are counted three years which he passed with the Spitzbergen expedition in connexion with which he was decorated with a Swedish order for scientific services. Two years ago he was appointed senior medical officer on board the *Peresviet* in the Far East, but on his arrival there he was transferred by Admiral Scrydloff, then on the station and now again on his way there, to the *Petropavlovsk* where he remained until his death. He was married and leaves a widow and two young children. He obtained his doctor's degree in 1895.

DISEASE IN WAR.

In a lecture given on March 15th (states the *Novoe Vremya*) before the Society of Investigators of Military Science by Mr. V. N Okunev on infectious diseases in war and the struggle with them he said, *inter alia*, that the present theatre of war was an especially dangerous one. Inkow, for example, was recognised by various authorities as a plague centre. It raged there with varying intensity, and there were other such centres in Mongolia and Korea. In the Amur district cholera was common whilst in Korea small-pox might be called permanent. And of course besides the diseases named there were typhus fever and dysentery to fear. The wells in these countries were a difficult question as they had not been examined and might therefore be dangerous. Filters not being always trustworthy he recommended boiling the water. The lecturer did not conclude without a warning against the careless use of preserved foods.

THE ARMY JOURNAL OF THE BRITISH EMPIRE.

The proposal to issue a new military journal under War Office auspices, which has been set forth by direction of the Army Council in a special Army Order, has given rise to a good deal of comment but the idea strikes us as being a good one and well worthy of trial. Other nations —France and Germany, for example—possess official journals of the kind. The design of the publication is a bold and broad one—namely, to deal with subjects of a professional and scientific nature, to encourage the study of military science and history, and to circulate information likely to promote a knowledge of the principles of imperial defence amongst all ranks and all arms of the military forces of the Crown. Whilst upon this subject we may say that the numbers of the *Journal of the Royal Army Medical Corps* for March and April show that the journal is growing in scientific and general interest.

THE WAR IN THE FAR EAST.

Press reports state that many of the Japanese troops in Korea are suffering from symptoms resembling those of beri-beri. This disease has long been known to exist along the south-eastern coasts of Asia and in Japan. In THE LANCET of May 2nd, 1896, p. 1238, we gave some account of an outbreak which occurred in the year 1894 in the Fiji Islands, all the patients being Japanese labourers of whom about 300 were imported for the purpose of working on sugar plantations. The Japanese known to be attacked were 268 in number, of whom 65 died, and in February, 1895, the whole of the survivors were sent back to Japan. The disease was entirely confined to these immigrants, not spreading either to the native Fijians or to the imported Indian labourers. The medical officers of the Japanese army will no doubt do everything that may be possible to arrest the disease in the present circumstances.

THE ROYAL NAVY LIST.

The April issue of the "Royal Navy List," which is published by Messrs. Witherby and Co., 326, High Holborn, London, W.C., contains appointments, promotions, retirements, and such like details bearing date as late as March 26th and in the admirable "Current History of the Royal Navy," a comparatively new feature of the List, we notice that there is a reference to the lamentable accident to the submarine A 1. The war and meritorious services of officers of the Royal Navy, Royal Marines, and Royal Naval Reserve are arranged in a manner which admits of easy reference, not a small matter when it is remembered that the names of some 10,000 officers are dealt with. The book is full of information on all matters connected with our first line of defence.

MILITARY MEDICAL INTELLIGENCE.

While the Army Medical Service may not be disposed to regard with any favour the position recommended to be assigned to it in future by Lord Esher's Reconstruction Committee the proposal to attach an officer of the Royal Army Medical Corps, who will travel when necessary, to the section of the Director of Military Operations which deals with intelligence will be recognised by all as a necessary and valuable recommendation.

DEATHS IN THE SERVICES.

Surgeon-Colonel George Cochêt Chesnaye, I M.S. (retired), at his residence at Bournemouth in his 67th year. He entered the service in 1859.

LITERARY INTELLIGENCE.—A treatise by Dr. R. R. Rentoul, entitled "Trachoma (Granular Conjunctivis)" has just been issued by Messrs. Cornish and Sons, Lord-street, Liverpool.

THE ROYAL BRITISH NURSES' ASSOCIATION.—The fifteenth conversazione of this association will be held at the Portman Rooms, Baker-street, London, W., on Tuesday, April 26th, at 8 P.M. Princess Christian has signified her intention to be present. The band of the Grenadier Guards will play a selection of music. Tickets—members, 2*s.*; nurses (non-members), 2*s.* 6*d*; guests, 5*s.*—can be obtained from the secretary, 10, Orchard-street, London, W.

Correspondence.

"Audi alteram partem."

THE USE OF HOT BOTTLES AFTER SURGICAL OPERATIONS.

To the Editors of THE LANCET.

SIRS,—I should like to call attention to a matter in connexion with the nursing of surgical cases which is of the highest importance. In directions to nurses, especially in laparotomies, a great point is made after the operation of packing the patient with hot bottles. No statement of the temperature of the hot water in the bottles is vouchsafed and in the absence of such grave risks are run. Bottles filled with water practically at the boiling point are placed in close contiguity to a semi-conscious patient and even the ordinary covering of a blanket may not suffice to protect the skin. The danger has been very forcibly brought home to me lately and inquiries amongst professional friends have resulted in my hearing of 17 cases of burns which have recently occurred from the practice. I thus feel sure that surgeons ought to be a great deal more explicit in their instructions regarding this detail of the treatment of their patients. I am, Sirs, yours faithfully,

Oxford, April 18th, 1904. H. P. SYMONDS.

THE "N" RAYS AS A PROOF OF DEATH.

To the Editors of THE LANCET.

SIRS,—With reference to Dr. John Munro's letter suggesting that the absence of "n" rays might be used as a proof of death, allow me to point out that it seems advisable at present to draw a distinction between the rays under investigation by Blondlot and those discovered by Charpentier. The former are of interest to the physicist, being generated by the sun, Nernst electric lamps, steel under tension, &c.; while the latter, proceeding from living muscle and nerve under strain, are of physiological importance. I have experimented with muscle rays only and it is because their objective existence has lately been the subject of entirely negative experiments at Glasgow and elsewhere that I am asking you kindly to afford me space for this letter.

In order that the existence of muscle rays may be made evident in the most convincing manner the following conditions must be present:—1. A powerful generator of the rays. Presumably this will be a muscular man or animal. 2. A fluorescent screen the luminosity of which will increase and die away rapidly, so that the connexion between cause and effect can be easily noted. 3 A good receiver—i.e., vision naturally capable of detecting a small change of luminosity—used under conditions which render it as sensitive as possible. The common cause of bewildering results is the natural tendency of everyone to involuntarily open the eyes wider when expecting to see an increase which may not be forthcoming and therefore to interpolate false answers amongst real ones. I have by practice acquired some expertness in observation and shall be most pleased to give a demonstration of the objective existence of the rays to anyone who has failed in his experiments. I will ask him to bring up his hand and stretch the muscles of the wrist at uncertain intervals in a completely dark room behind a cardboard screen, made of two large sheets each one-sixteenth of an inch thick and separated by three-sixteenths of an inch air space. On the face of this the luminous disc will be fixed, and by observing it from a few feet in front I will undertake to tell him when he brings his hand up. If convinced there is no delusion about the matter I think the medical profession will take the investigation and application of "n" ray phenomena seriously in hand. I am, Sirs, yours faithfully,

Hatton-garden, E.C., April 18th, 1904. LESLIE MILLER.

PS.—Since writing last night I have heard from someone who was present at Blondlot's demonstration of "n" rays before the French Physical Society on April 15th that he was able to show the effect of a coiled-up watch-spring and a stropped razor—i.e., metals under tension—as sources of the rays. I have just repeated this experiment with a powerful clock-spring, held in the jaws of a test-tube holder and waved behind my cardboard screen. The effect is more evident than with strained muscles. The luminous strip unmistakeably brightens up even when the clock-spring is still some inches from it with the two thicknesses of card between. Professor Blondlot appears to have given a convincing demonstration.—L. M.

THE INTERNATIONAL CONGRESS OF SCHOOL HYGIENE.

To the Editors of THE LANCET.

SIRS,—In a note from your Berlin correspondent in THE LANCET of April 16th, p. 1086, I notice an announcement that the next International Congress of School Hygiene will be held in London under my presidency. Like all others interested in the subject, I am glad that the Congress has accepted the invitation to hold its next meeting in London in the first week of August, 1907, but although I have been appointed president of the International Committee the arrangements for the next meeting have been left very much in the hands of the English Committee and we hope to secure as president of the Congress at its next meeting some one of such position that even headmasters of public schools may be ready to work under him. The French delegates to the Congress, whilst expressing to me their [illegible] should not have taken place in [illegible] Congress to meet in Paris in [illegible] ourteous and kindly manner declared that they will do everything in their power to make the London meeting a success. The object of the Congress is one of vital importance, and I am sure that the English will collaborate not only with their French colleagues but with those from every country to render the next meeting in London a success, in forming bonds of friendship between the teachers of all lands, as well as forwarding the other objects for which the Congress has been established. I am, Sirs, yours faithfully,

Stratford-place, W., April 20th, 1904. LAUDER BRUNTON.

ON SYPHONAGE IN THE LARGE INTESTINE.

To the Editors of THE LANCET.

SIRS,—I am glad to find that Dr. A. Keith has examined my book and I must ask others interested in the subject to do the same before passing judgment on my views, for I cannot quite accept my critic's exposition of them and the space I can occupy here is insufficient to do them justice. 1. I think no one can deny that the large intestine with its [illegible] its long descending limb is (given [illegible] walls) structurally a syphon and I [illegible] rubber tubing bent to reproduce its flexures. With glass I was hampered by the limitations of the glass bender and I had to be content with equivalent, instead of identical, curves But I did more, I imitated the V colon and found, as I expected, that as long as its angle was higher than the outlet of the tube syphon action was unimpaired As for the consistence of the contents, I do not claim syphon action unless these are "capable of flowing" (p. 41), but I succeeded perfectly well with thick treacle and other dense substances. 2. Dr. Keith is also mistaken in thinking that I claim that syphonage explains the peculiar course of the colon, for it is obvious that since syphonage cannot exist with the trunk horizontal, syphonic evolution could not have been a factor in producing this course What I suggest is that man has only been able to maintain his existence in the erect posture because the colon happens to admit of syphonage 3. I am not so foolish as to deny the existence of peristalsis in the human colon; all I affirm is that it is inadequate *per se* to effect propulsion of the contents of the ascending colon in the erect position. In [illegible] act in opposition to the force of [illegible] consistent with i [illegible] in the question, [illegible] to counterbalance the intra abdominal pressure? It cannot be *proved* to be insufficient, because the human colon is never [illegible] rtuary [illegible] these [illegible] ough I cannot *prove* the resistance to be sufficient I can bring forward much evidence in support of it. For instance, the daily morning evacuation is due to the resumption of the erect position in which alone syphonage is possible. If it were due to peristalsis it would follow the heaviest, or perhaps each, meal in the day. Morning diarrhœa is explained in the same way as is also the curious fact pointed out by Brunton that a morning saline will not act satisfactorily if the patient gets back into bed again. Syphonage is necessarily followed by a partial vacuum in the cæcum since the latter is emptied much more rapidly than it can be refilled. This explains the frequency with which the cæcum is found nearly empty (under peristalsis it would be fuller than any other part of the bowel) and it also explains the occurrence of ileo-cæcal intussusception.

Dr. Keith says that he cannot conceive how contraction of the tæniæ can increase rigidity except by shortening. It does so, as I explained, by the deepening and doubling in of the internal inter sacculan ridges. In the case of a transverse colon which measured *in situ* only ten inches, but which, when drawn out, measured 20 I found that each ridge projected inwards for half an inch, while its thickness, of course, was double that of the colon walls. The effect of this in preventing collapse must be very great and it is aided by the fulness of the circular blood vessels and by the stiff tæniæ themselves which act like bridges from one full part of the bowel to another full part. Altogether I think it must be admitted that even the evidence given above points to the existence in life of sufficient rigidity to admit of syphonage. If more is required it will be found in the book.

I am, Sirs, yours faithfully,

April 16th, 1904. R. W. LEFTWICH.

THE EVIDENCE FOR THE HETEROGENETIC ORIGIN OF BACTERIA.

To the Editors of THE LANCET

SIRS,—In what purports to be a review of my "Studies in Heterogenesis" in THE LANCET of April 16th, p. 1060, the writer tells your readers nothing as to the actual contents of my work, though he gives them very false notions as to its purport and as to the methods pursued in regard to the particular questions to which he refers. He attributes to me conclusions "which, if rightly established, must," he says, "of necessity cause the whole fabric of bacteriology, infection, and hygiene to fall upon, and to annihilate, the multitude of investigators who have helped to build upon the foundations laid by Pasteur and to cause the name of Pasteur himself to be erased from the roll of fame." This seems to me utter nonsense and as unjustifiable as it is nonsensical. Let your reviewer quote anything he can from my book which would in the least justify what he says. The above surprising statements are followed by this further remark: "To review this elaborate book at length would be but to attempt to fight over again the battle ably fought, and we believe won, by Darwin, Pasteur, and their disciples." I never knew that Darwin had ever written a line on bacteria or heterogenesis, and on consulting the very full index to the sixth edition of "The Origin of Species" my impression was confirmed. Neither of these words are to be found therein. Yet your reviewer says his work in this direction "is, or ought to be, a matter of common knowledge"

A little further on this very unscrupulous and careless writing is followed by a statement directly untrue in its bearing upon my Section XXIII. on "The Origin of Bacteria and their Allies by Heterogenesis." He says: "The antiquated methods which still find favour in attempts to re-establish the *de novo* origin and interchangeability of lowly forms of life find no place in modern bacteriological technique." But the work which I have recorded in the section indicated, dealing with the origin of these organisms, was conducted almost throughout under strict antiseptic precautions. I trust, therefore, that you will permit me to make two quotations from that section in order to show, what your reviewer has not done, the kind of evidence adduced, and to correct the very erroneous impression which he has disseminated.

As an illustration of the appearance of one of the bacterial allies within closed vegetable cells, which the doctrines of the day declare to be germless, I would cite (from p. 301) the following experiment. "A small new potato, after careful washing, was placed in a small tin with a very tightly fitting cover and allowed to soak in 10 per cent. formalin for 20 minutes, the fluid having been shaken about several times so as thoroughly to wet the whole internal surface of the tin. The fluid was then poured off, leaving the surfaces wet with the solution as before; the tin cover was very tightly jammed down, and the vessel was placed within a copper incubator at a temperature of 75° F., and allowed to remain there for eight weeks. ...... When taken out and examined the cut surface of this potato presented just the same characters as in the others; the whole substance was firm throughout, there was no shrinking, and the central portion was rather darker than the other parts which showed the usual mottling. ...... On microscopical examination a large number of the cells scattered throughout the sections were found to show the most delicate branching tufts of a new kind of microphyte, probably a species of *Cladothrix*, which had taken the stain slightly, and such as are shown in Fig. 196 (× 500). These tufts were mostly seen to be sprouting from the external surface of the primordial utricle, where it had shrunk away from the cell wall. No Bacteria and no ordinary mycelia were found in either of the sections, though they were most carefully examined."

This may be taken as typical of many other experiments recorded in this section in which either bacteria or one or other of their allies were found within closed vegetable cells in the central portions of tubers or fruits. It is true that, according to Pasteur, the cells of healthy plants are free from any such micro-organisms. He has distinctly affirmed this on several occasions, and microscopical examination of them in their fresh state has convinced me of the truth of this proposition. Thus, whilst agreeing with Pasteur as to the germless condition of the healthy vegetable cell, I have gone further and have shown what may occur in such cells when they have been long kept under unnatural conditions. Now, what view does your reviewer wish to take in regard to these facts? Is he prepared to help to erase the name of Pasteur "from the roll of fame"? Has he independent evidence to show that Pasteur was wrong? and if not, How does he account for the appearance of these organisms within multitudes of the closed vegetable cells in the central parts of the tubers or fruits? The antiseptic has been proved to be adequate, since no organisms have ever appeared upon the surface or in the superficial layers of cells. Then, again, he cannot say the organisms were not there and that I must have been mistaken. The photographs afford an effectual check to that kind of statement.

I should like also to cite another observation, often repeated, which even in the absence of antiseptic precautions (here impossible) seems to me to be of a very convincing nature. At p. 307 I have pointed out the fact that the minute spines on the abdominal appendages of a Cyclops show nothing within but structureless protoplasm having a glass-like appearance, and I have described the very simple conditions under which, on the death of the animal, we may see minute *motionless* specks gradually appear within this structureless matrix. The description continues thus: "Still later we may see some of these specks growing into bacteria, as in Fig. 200, B (× 700), which is a representation of A after four days. At last the whole interior of the spine becomes filled with distinct Bacteria, as may be seen in C (× 700)." Of course it is easy for a person absolutely convinced that living units cannot arise *de novo* at the present day (whatever he may believe in regard to a far remote past) to attempt to explain away the cogency of such observations. But how does he do it? Only by postulating one or other assumption, not only unsupported by evidence but actually at variance with existing knowledge. He will ask you to believe that the tissues of this little animal are absolutely pervaded in their remotest parts by *invisible* germs of bacteria, even though he is aware that all known bacterial germs are readily visible under a power of 700 diameters, and if present would have been readily recognisable in the healthy spine when the observation was commenced Or he will wish you to believe that these minute germs, though devoid of all signs of motility, have yet been able to get from the drop of distilled water through intention to ·us envelope of the spine. Surely such reliance will play a s unsupported hypotheses is, from the point of nurses (non-mene, altogether immoral.

from the secretar attempt to say anything concerning other ·terogenesis dealt with in this work, as undoubtedly the question of the origin of bacteria and their allies is that portion of the subject which has the most important bearings upon medical science. I must, however, thoroughly repudiate what is said in conclusion by your reviewer when he speaks of the work as "the best possible statement of the case against the claims of modern bacteriology and unicellular biology." I have said absolutely nothing tending to minimise the enormous value of bacteriological work, and I defy your reviewer to quote anything to that effect.

I am, Sirs, yours faithfully,
Manchester-square, April 17th, 1904. H. CHARLTON BASTIAN.

*** Dr. Charlton Bastian is wrong in using the adjectives "unscrupulous," "careless," "unjustifiable," "nonsensical," and "untrue" because our reviewer does not hold the views ennunciated in his book. That an index to one of Darwin's books does not include the words "bacteria" or "heterogenesis" leaves unchanged the fact that Darwin's teaching generally is at absolute variance with Dr. Bastian's theories—and this is all that our article indicated. In reviewing Dr. Bastian's book we showed him, as a member of the medical profession distinguished in other fields of inquiry, a consideration which certain British and foreign learned societies have refused to extend towards the views that he expounds. Our courtesy has been entirely misconstrued.—ED. L.

REMARKABLE RESUSCITATIONS.

To the Editors of THE LANCET.

SIRS,—In your interesting leading article on Remarkable Resuscitations in THE LANCET of April 9th, p. 1005, you touch upon the possibility of premature burial. Some years ago I investigated this subject and came to the conclusion that although premature, or live, burial was not impossible yet that, on the other hand, in no single instance could I discover conclusive evidence that premature burial had taken place. Tales there are in plenty of terrible tragedies among the tombs but I failed to find one that would satisfy the ordinary proofs required, say, in a court of law. This investigation I published in the form of a small book entitled "Premature Burial, Fact or Fiction" (Baillière). I venture to call your attention to this fact, which has apparently escaped the notice of your leader writer as he makes no mention of this English book, although continental authorities are quoted.

I may add that one case of premature burial which was reported from America and widely quoted by the alarmists in the United Kingdom was condemned as a fable in my book on internal evidence alone. Some time afterwards an American medical man journeyed to the place where the incident was reported to have taken place and from inquiries entirely confirmed my view of the case.

I am, Sirs, yours faithfully,
Hanover-street, W., April 12th, 1904. D. WALSH.

THE METHODS OF ANTIVIVISECTIONISTS.

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Murrell's letter in your issue of April 2nd it is only fair to him to say that he is quite correct in stating that he was an unintentional contributor to the book to which he refers. Let me add that this point was made clear in the book itself. It is there stated—first, that Dr. Murrell is unconnected with the London Antivivisection Society; secondly, that the article in question was copied from an American periodical; and thirdly, that "this article was not written by Dr. Murrell for this book."

I am, Sirs, yours faithfully,
SIDNEY TRIST, Secretary.
The London Antivivisection Society, Regent-street, S.W.,
April 14th, 1904.

*** The accuracy of Dr. Murrell's statement required no endorsement from the secretary of the London Antivivisection Society. To some people an explanation might seem due to Dr. Murrell, and to the editors who had previously published Dr. Murrell's work, for the annexation of that work, but our experience is that in matters of courtesy the antivivisection propagandist is a law to himself.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Dufferin Fund.—The Increasing Plague Mortality.—The Character of the Volunteer Force in India.—An Enterprising Nursing Association.—The Report of the Army Sanitary Commissioners.

THE report of the Dufferin Fund for 1902 recently issued gives a record of useful work. Of the women engaged 41 hold qualifications of the United Kingdom, 78 are classed as of the second grade, being trained and holding qualifications obtained in India, and 256 act as hospital assistants. In addition there are more or less trained midwives working under the association. The subcommittee appointed has recommended that the Government should raise the standard of female medical education in the medical schools and that all lady doctors should undergo practical training in a special women's hospital before obtaining their degrees. At the present time there are 114 Eurasian and native ladies being trained as assistant surgeons and 95 as hospital assistants, besides 281 as nurses, dais, and compounders. Up [illegible] been provided for several cent[illegible] Lahore, Agra, Benares, and [illegible] of women and children treated in the zenana hospitals, wards, and dispensaries throughout the country during the year was 1,792,000 which, it appears, was only a very slight increase over that of the previous years.

[illegible] th[illegible] pl[illegible] week as against 29,236 for the corresponding week of 1903. The local figures are important. In the Punjab there were 10,174 deaths as against 6431 in the previous seven days; in the United Provinces, 9427, as against 8504; in the Bombay Presidency, 7687, as against 7140; in Bengal, 4797, as against 4386; in the Central Provinces, 2804, as against 2290; in Central India, 1640, as against 955; in Rajputana, 1033, as against 621; in Kashmir, 526, as against 405; in Bombay city, 849, as against 925; and in Calcutta, 295, as against 230 In the last case later returns show 474 deaths for the week ending March 26th. The increase of plague is general throughout India, but it is curious to note that while in the Bombay districts plague seems to continue virulent all the year round, in the North-western districts it dies away in June and July to reappear a few months later in each year. There is no hiding the fact that plague is now worse in India than ever it has been

A recent inspection of volunteers by Lord Kitchener called forth the opinion from him that every Englishman by birth or descent should be a volunteer. It is to be hoped that under his ruling some improvement in the physique as well as in the status of the force will be brought about. The Government and the military forces have hitherto shown very little interest in volunteer movements. It is generally forgotten that by the Army Regulations the force should be a European one. This has not been adhered to. It is not very long ago that nearly every European in the Hyderabad (Sind) corps resigned and that the inspector general drew attention to the fact that some corps, especially the Allahabad and Poona Rifles, had ceased to be European in character. It does not appear that the Government has taken any action in this matter, but while so much attention is bestowed on the native troops and the permitted contingents of the native States very little is done for the volunteers. I had occasion to draw attention to the physique of those picked corps which attended the Delhi Durbar but the ordinary ranks of most corps are lamentable.

The first annual report of the Bengal-Nagpur Railway Nursing Association shows what can be done by an enterprising organisation. A bungalow was transformed into a hospital, a qualified nursing sister and nurse from England were appointed, and patients from the different sections of the line were received. The whole scheme is now being worked on a commercial basis and furnishes an organised medical and nursing staff for the whole of the employés. The Europeans in isolated stations must feel great comfort in having such assistance available.

It would be a service to draw the attention of Members of Parliament to the absurdity of issuing the report on the sanitary measures in India for the year 1901 towards the end of 1903. This annual report of the army sanitary commissioners is not only belated but is merely an abstract of other reports issued long before. Nearly all the information given is contained in the report of the sanitary commissioner with the Government of India and the added memoranda of the army commissioners merely repeat what is given in the early pages of the same report. The report when issued is practically two and a half years old.

March 31st.

CHOLERA IN MESOPOTAMIA AND PERSIA.

(FROM THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

THE cholera outbreak at Bagdad is declining, if it has not indeed come to an end; that at Basra, on the other hand, is increasing and the disease has recently crossed the Turco-Persian frontier and appeared on Persian territory. The following are the returns for Basra since the date of my last letter (THE LANCET, March 26th, p. 897):—

From March 13th to 19th ...	25 cases ...	27 deaths.
,, ,, 20th ,, 26th ...	21 ,, ...	20 ,,
,, ,, 27th ,, 31st ..	36 ,, ...	36 ,,
,, April 1st ,, 10th ...	37 ,, ...	28 ,,

A considerable number of cases continue to be hidden from the authorities during life and only come to their knowledge after death. Thus in the above four periods the numbers of cases returned as "trouvés morts" were respectively 13, 8, 24, and 13.

At Bagdad the following are the weekly returns of cholera cases and deaths since the reappearance of the disease there on March 7th:—

On March 7th	2 cases	0 deaths
From March 8th to March 13th	19 ,, ...	11 ,,
,, ,, 14th ,, 20th	16 ,, ...	15 ,,
,, ,, 21st ,, 27th	9 ,, ...	4 ,,
,, ,, 28th to April 3rd ...	6 ,, ...	13 ,,
On April 6th	1 ,, ...	0 ,,

The case reported on April 6th is the only one which has been observed in Bagdad between April 3rd and 12th and it is therefore hoped that the disease may really have died out there.

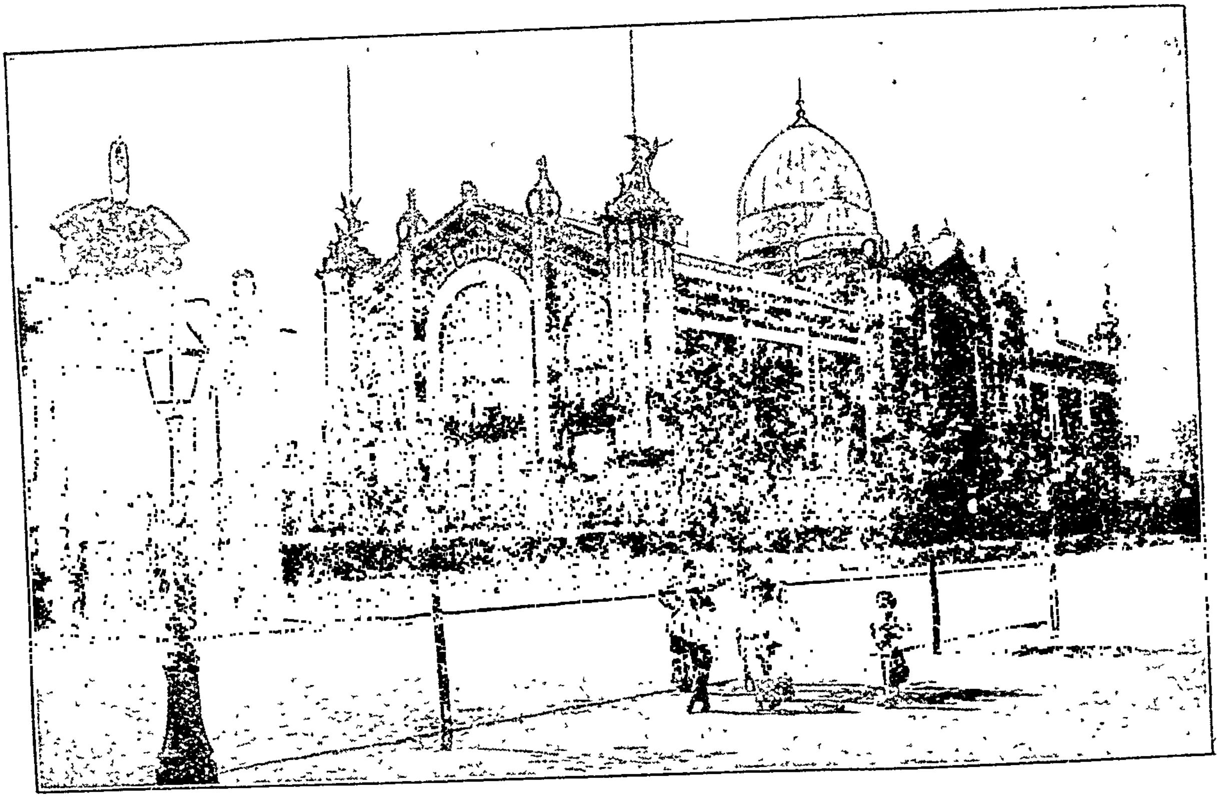
On April 5th it was reported that cholera had appeared at Kermanshah, on the Persian side of the Turco-Persian frontier. On the 9th it was stated that six cases and four deaths had occurred up to that date. No further details have yet been received but the fact that the infection has crossed the frontier and entered Persia is a regrettable one. On several occasions during the last few months there have been rumours that cholera had reached the important town of Meshed in Northern Persia but the rumours have not been confirmed and were probably not true. But should the disease spread from Kermanshah through Persia and ultimately reach Meshed the danger would arise of its passing thence across the Perso Russian frontier and spreading by the Transcaspian Railway eastwards to Siberia and westwards to European Russia, as it did in 1892.

Constantinople, April 15th.

LATIN-AMERICAN CONGRESS OF MEDICINE AND HYGIENE.

IN THE LANCET of Jan. 23rd we gave a preliminary account from the pen of our special correspondent, mainly as regards the medical side, of the Latin-American Congress of Medicine and Hygiene which is still, so far as the hygienic section is concerned, in progress at Buenos Ayres The Congress opened on April 3rd and the medical portion of it closed on April 10th, but the exhibition of hygiene which opened at the same time as the medical portion remains "in being" until May 30th. We have now before us the official programme of the hygienic exhibition of which Dr Emilio R. Coni is the president and Dr. Samuele Gache is the secretary. The architect is Virgilio Cesari. The principal building in which the exhibition is housed is the Pabellon Argentino of which we give a

FIG. 1.



The Pabellon Argentino.

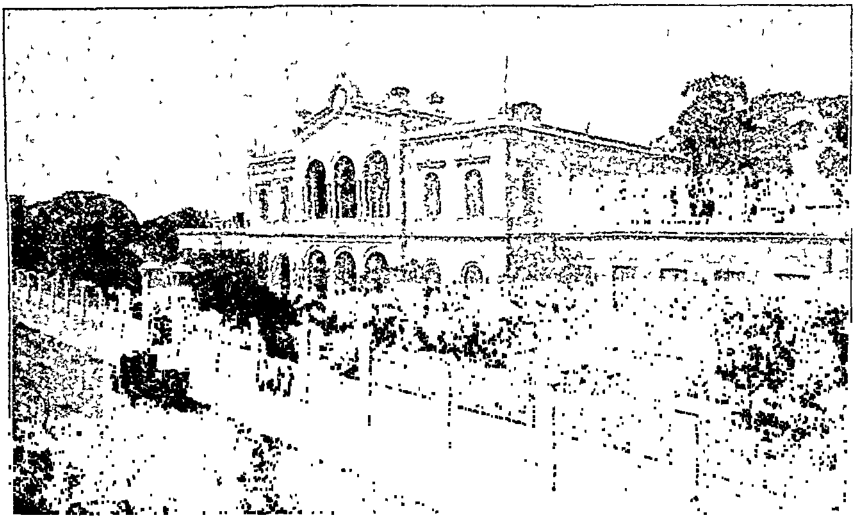
FIG. 3.



The San Roque Hospital

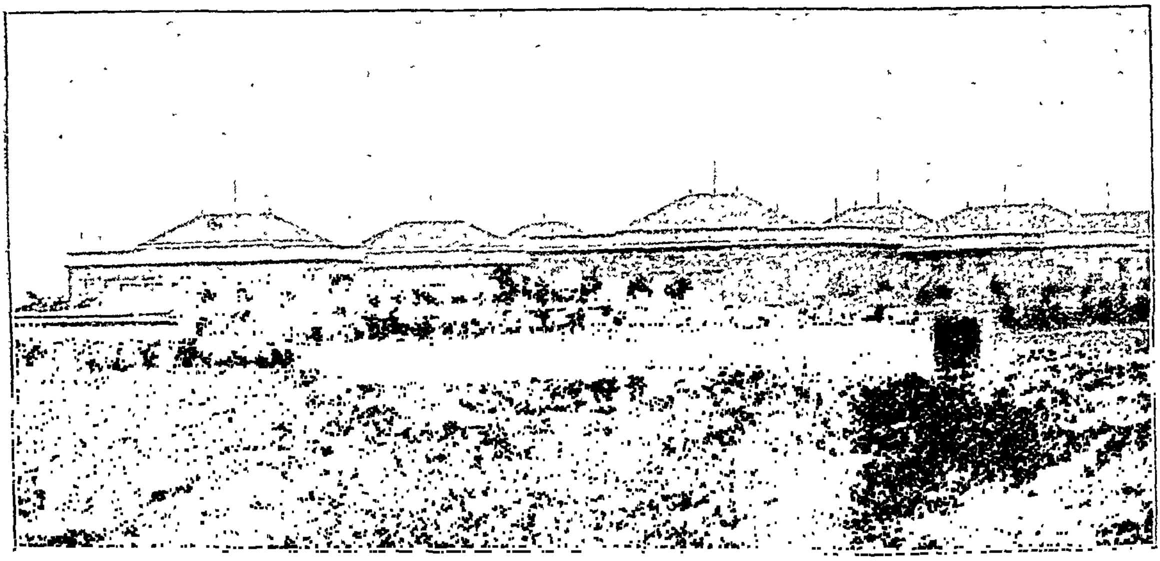
FIG. 4.

Interior of the San Roque Hospital.

view (Fig. 1). This building includes a floor space of 1267 square metres and has been, as will be seen, erected in a somewhat ornate style. In addition to this the principal building are five others comprising 1452 square metres of floor space. One of these is allotted to military hygiene and sanitation, another to the municipality of Buenos Ayres for an exhibition of apparatus and the like concerning public health, and another is devoted to an exhibit from Uruguay and Chile.

The exhibition is divided into 15 sections which are as follows:—Section 1: Instruments and apparatus for hygienic investigation and demonstration, such as apparatus for the analysis of air, soils, water, drinks other than water, and foods. There is also an exhibit of apparatus for the study of ventilation, the humidity of walls, photometric instruments and bacteriology, chemistry, and physiology in so far as these apply to hygiene. Section 2 is devoted to sanitary statistics and demography; Section 3 deals with the all-important question of water-supply; and Section 4 with the no less important question of drainage, sewage, and the like. Section 5, a very comprehensive section, has for its subject the hygiene of the dwelling and hence includes drainage, lighting, warming, ventilation, and many other matters. Section 6 deals with the hygiene of streets, Section 7 with baths and washhouses, Section 8 with clothing, Section 9 with food and drink, both fresh and preserved, and Section 10 is concerned with infant life protection. Section 11 deals with the question of the sick and wounded, including removal of infectious cases and hospital hygiene, and Section 12 is devoted to epidemiology and the prophylaxis of transmissible diseases. Here will be exhibited bacteriological apparatus, serum therapeutics, disinfecting apparatus, and much other cognate material. Section 13 deals with the disposal of the dead; Section 14 with the hygiene of barbers' shops; and, finally, Section 15 is allotted to industrial and professional hygiene.

FIG. 5.



The Buenos Ayres Isolation Hospital for Infectious Diseases.

Many firms have applied for space for exhibits, but only five or possibly six seem to be British. The exhibition should be of great interest if the actual exhibits carry out the programme in anything like its entirety and Buenos Ayres is certainly a well-ordered city from a hygienic point of view.

Our other illustrations show the Faculty of Medicine where the Medical Congress sat, the interior and exterior of the San Roque Hospital, and the isolation hospital. San Roque or Roche was one of the saints who was specially
d against the plague, the others being the Blessed
St. Antony, and St. Sebastian, so it is natural that a
hould be dedicated to him. San Roque was a
other medical saints, who were of the con-
n type, were St. Cosmas and St. Damian,
n.

THE FIRST INTERNATIONAL CONGRESS OF SCHOOL HYGIENE.

(FROM OUR SPECIAL CORRESPONDENT.)

THE SECTIONAL MEETINGS.

THE meetings of the Congress were arranged in seven sections and dealt with the following subjects: Group A, School Buildings and the Furnishing of the School Room; Group B, the Hygiene of Residential Schools, the Methods of Hygienic Investigation and Research in Schools, and the Physiology and Psychology of Educational Methods and Work; Group C, Instruction in Hygiene for Teachers and Scholars; Group D, Physical Education and Training in Personal Hygiene; Group E, Contagious Diseases, Ill-health, and Conditions affecting Attendance; Group F, Special Schools, including Feeble-minded, Blind, Deaf, Dumb, Cripple, Invalid, and Exceptional Children; and Group G, Out of School Hygiene, Holidays, Camps, and Schools; the Relations of the Home and School and the Hygiene of the Teaching Profession.

The sectional meetings of Congress held at Nuremberg took place in the Royal Industrial School—a building admirably adapted for the meeting of such a congress as it supplied a sufficient number of rooms for the various sections and accommodation also for the museum. Nothing but praise can be given for the general administration of the Congress. There was no undue delay in obtaining all information required and the daily publications. The one noticeable defect in the sectional meetings of the Congress was the ventilation of the rooms. The school building is perfectly new, is warmed and ventilated *on the most modern principle*, and yet without the rooms being unduly crowded the atmosphere was such that it became in some rooms unbearable. In other rooms in which the chairman and others did not object to an open window the atmosphere was better, but even that did not efficiently ventilate the room. It is also to be regretted that the chairmen in the various sections exercised so little control over the length of time allotted to the reader of a paper and it not infrequently happened that the time limit was exceeded by ten or 15 minutes, the result being that many papers were crowded out. It may be said, however, that all the sections were well attended. Many of the papers read were fully discussed and criticised. The papers generally were of interest, some of practical value and others only of academic interest, and were discussed not only by medical men but also by schoolmasters.

Dr. **LIEBERMANN** (Budapest) spoke on the Duties and Education of the School Medical Officers. He said that the scholar of the higher classes needed as much medical supervision as did the children in the elementary schools and in this respect no difference should be made between the lower grade or higher grade schools. The school was not a sanatorium but an institution for the development of knowledge and it was the duty of the school to see that this knowledge was not acquired at the expense of health. There was, however, no doubt that attendance at school was accompanied by dangers just as dangers accompanied the workmen in the factory. And as the manufacturer was obliged by every possible means to provide against accident, so it was the duty of the school authorities to prevent as far as possible the spread of disease in school. This duty had been greater since attendance at school was now compulsory. He considered, however, that it was the duty of the school not only to guard the pupils against disease but to teach the pupils the necessity of hygiene and this was far more important than a great deal of book work. If hygiene were taught in schools it was carried into family and home life and benefit resulted to the community at large. Opportunity should be taken to warn the scholar against immorality and excess. It was the duty of the medical officer to examine a scholar when admitted into school, but the systematic weighing and measuring of the scholars, although it might be of statistical value, was not the duty of the school. He stated that in Hungary every practitioner before he could become a school medical officer must undergo a special course of hygiene. When school hygiene was carried out in this way then it would become an educational method of the greatest value.

Professor **HUEPPE** (Prague) read a paper on the Prevention of Infectious Disease in Schools. In all infectious diseases the predisposition was of first importance. The presence of this predisposition was the origin of all infection and therefore it was of the greatest importance to increase the power of resistance. The younger the individual the greater the liability to infection. As soon as any symptoms were noticed everything should be done to prevent the spread of infection. This was one of the most important duties of the school medical officer. A child who had a suspicious illness must be excluded from school and if required the whole class must be closed. The home conditions of the child should be inquired into, since it often happened that the disease was carried from the home to the school. The insanitary dwellings of the poorer classes had much to do with the spread of infection. If cholera, dysentery, or typhoid fever was proved to be acquired in the school then it was certain that some marked defect in the hygiene of the drains, closets, or water-supply was present. The most powerful weapon against infectious diseases was cleanliness. The infectious disease of school life might be divided into three groups, the most important of which, measles and whooping-cough, might be considered typical school infections. Mumps and chicken-pox were placed in the second group. In the third group came diphtheria and scarlet fever. The last two, although dangerous diseases, were from the school point of view of less importance than the diseases of the first two groups. Small-pox might be disregarded, since vaccination had made it almost extinct. With regard to measles and whooping-cough, the susceptibility and disposition of the individual were of greater importance than the infection and those diseases were infectious at a time when the symptoms were hardly recognisable. Owing to the sudden outbreaks of measles and whooping-cough it was important that the classes should not contain more than 40 or at the most 50 children. Closure of schools and isolation were most important in these diseases. Mumps and chicken-pox were easily combated by isolation. In tuberculous infections the most important factor was the power of resistance of the individual; it was therefore the duty of the school by strengthening the body to increase the power of resistance. The school had not only to deal with the development of the mind but also with the whole development of the man. The speaker advocated that children should be sent to holiday camps by the sea and elsewhere and he thought that in this way the number of cases of pulmonary infection would become less.

Dr. G. E. **SHUTTLEWORTH** (London) read a paper on the Educational Treatment of Epileptic Children in Great Britain. He said that up to the present time the education of epileptic children had been undertaken by private enterprise and little had been done by the Government, although the Act of Parliament of 1899 provided for the elementary education of defective and epileptic children. He had examined some 470 cases of epileptic children and these he divided into four classes: (1) 17 per cent. were fit to continue in the normal school; (2) 27·5 per cent. were so far mentally impaired as to need separate instruction in the special classes for defective children; (3) 40 per cent. required to be cared for and taught in a residential institute for epileptics; and (4) 15·5 per cent. were unfit for any education and required only medical and nursing care He calculated that accommodation was required for nearly 3000 epileptic children and that at the present time there was not accommodation for more than 200. He was of opinion that epilepsy was no disqualification for education but that the length of school hours should be reduced and that no hard and-fast rule could be laid down for the education of epileptic children but that each case must be considered by the medical officer in charge.

Dr. **CLEMENT DUKES** (Rugby) read a paper on the Organisation of Physical Education. He said that the physical development of the body was of importance for the mental development and that an energetic manhood could only be obtained by a healthy boyhood. He was of opinion that school games were important for the education of the boy, that such games should be made compulsory on all boys, and just as times were arranged for work in school so there should be a definite arrangement of play. A boy who did not play became dull and apathetic and became unfitted for the struggle of life. He was not in favour of Swedish exercises except in certain instances. Excessive exercise was as bad as deficient exercise and tended to stunt the body. He pointed out how necessary it was for a boy to train for his games and he stated that most accidents during play happened at the beginning of a season when a boy returned from holidays and in an untrained condition took up some violent form of exercise. The boy was an active animal and it was important to give him active employment or he would almost certainly find some occupation which might not only be useless but even dangerous. For young children he considered carefully arranged physical exercises most important, but it was to be remembered that the staying power of the young child was very limited.

Dr. F. **MAY DICKINSON BERRY** (London) read a paper on the Physical Examination of 1580 Children from Elementary Sch[illegible] to the Prevalence of Albumin[illegible]ildren examined were those who had gained scholarships given by the Technical Education Board of the London County Council to enable them to continue their education in higher grade schools. Each [illegible]o take up the scholarship had to [illegible] Tables of the average weight [illegible]e of these children were shown [illegible]ables from other countries. The London children compared favourably as regards height with all others; in weight they were slightly below both the Swedes and the Americans. The two points in the examination chiefly dwelt upon were (1) the large number of cases of slight lateral curvature of the spine (11 per cent. of the total number) which demonstrated the need for more gymnastic training and physical exercises than were at present to be had in our elementary schools; and (2) the occurrence of albuminuria in nearly 10 per cent. of the children examined. A considerable number of these were kept under observation for periods varying from one to five years. In more than half these cases the albuminuria had disappeared at the last examination; in many, however, it persisted at each examination and remained of a considerable amount. In no case was any deterioration in the general health recorded.

Mr. P. **SIDNEY SPOKES** (London) read a paper on the Care of Children's Teeth. He said that whilst it was important to insist upon the necessity of a good dentition it was equally urgent that the evils dependent upon the presence of diseased teeth should be recognised. Apart from the suffering caused by exposed pulps of teeth or abscesses at their roots there was the possibility of constitutional disturbance other than that brought about by prolonged pain. A septic state of the mouth might provide the material and absolute starting point of a general infection. Children were subject to many diseases which might be attributed to bad teeth. Many boards of guardians, and especially those in London districts, had, with the sanction of the Local Government Board, appointed dental surgeons during the past decade and he was sure that much good had resulted. The children in the public elementary schools were, however, left without conservative treatment and were in a much more neglected state than the Poor-law children. The only way to get preventive treatment adopted was by means of properly appointed dental surgeons to the schools and under the new Education Act it was to be hoped that something might be done for these children. Mr. Spokes advised that children should receive instruction as to the importance of sound teeth and the necessity of taking care of them; that in all Poor-law schools dental treatment should be compulsory; that in board schools it should be at first optional and later obligatory and that in public and private boarding schools there should be compulsory inspection on arrival with reports to parents when necessary; and that for all scholars the use of a tooth-brush, at least once a day after the last meal, should be enforced.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Coloured Milk.

AT a recent meeting of the health committee of the city the medical officer of health made a report on the extent to which milk which was intended for sale in the west-end of Birmingham was coloured in order that really poor milk might appear to be of good quality. From sellers in this part of the city a number of samples have recently been obtained which, in addition to being diluted with water, were coloured. It may be mentioned that the district in question contains a large proportion of the better class residences within the city boundary. On a recent Sunday 33 samples were taken in Edgbaston and Harborne which are two of the best suburbs of the city. Of these samples no fewer than 18, or 55 per cent., were found to contain colouring matter. The report of the medical officer stated that there might be some reason for adding colouring matter to sweets of various kinds and to butter and cheese in order to make them more uniform and presentable, but in the case of milk such addition is entirely unnecessary and the main object of it was to deceive the customer. In most cases milk is stored in a basin or jug and when so stored it is not easy to detect the presence of colouring matter, but if coloured milk is put into a tumbler until the cream rises it will be noticed that the skimmed milk is of a somewhat brownish tinge instead of the ordinary bluish one. The health committee, after considering the report, instructed the medical officer of health to draw the attention of all milk sellers in the city to this objectionable system of mixing colouring matter with their milk and to inform them that the health committee was determined to take the strongest possible measures to put a stop to it.

Oysters and Typhoid Fever.

In his ninth annual report as medical officer of health of Erdington Dr. A. Bostock Hill draws attention to the fact that three out of 30 cases of typhoid fever which occurred during the year were undoubtedly due to the consumption of oysters and other shell-fish. His report states that one case was particularly interesting because it occurred in a man who had been recently operated upon for appendicitis. During his convalescence he was advised to eat oysters. He did so and within the period of incubation became attacked by well-marked typhoid fever. In another case a woman became infected a fortnight after eating oysters, whilst in a third case, that of a man, it was found that he had been eating mussels on many occasions just previous to the incubation period of the disease. There is no doubt, therefore, says the report, that it is a most urgent requirement at the present time that power should be given by legislation to protect oyster layings and shell-fish beds from the sewage pollution which occurs so largely in estuaries and other places. The danger of acquiring typhoid fever from shell-fish has been proved up to the hilt and it is to be hoped that the recommendation of the Royal Commission on this subject will bear fruit at an early date.

Foresters' Homes.

At the recent meeting of the delegates in connexion with the Foresters' Convalescent Home for the Midland Counties it was reported that more patients than ever had been admitted during the year, the total being 316, an advance of 22 upon last year. At the same time the cost per head for maintenance had been slightly reduced. The results so far as the patients were concerned were as follows: able to work 176, improved 18, much better 1, no better 2, relapses 4, expelled 1, and extension 114. It was considered that the number of members able to work after leaving the home was very satisfactory. Some of the patients sent were not fit for the home and it was decided to urge the different lodges to exercise more care in this respect. It was also decided to shorten the period of extension except in cases considered urgent by the medical attendant.—The joint committee of Foresters and Odd Fellows appointed to consider a scheme for providing a sanatorium for consumptives reported that it had found a suitable site and buildings at Barnt Green, a place on the Lickey Hills, about ten miles from the city. The house, which is situated on three and a half acres of ground, had been built for a gentleman who suffered from consumption and who regained his health whilst residing there. To purchase the freehold and to furnish the house would cost £3000, of which £1000 would have to be paid in cash. The cost of maintenance would probably be from 25*s*. to 30*s*. per week per patient. In moving the adoption of this report the President, Mr J. H. Smith, reminded those present that 15 out of every 100 persons in this country died from consumption which attacked men in the prime of life. If submitted to the fresh-air cure in the early stages of the disease experience showed that from 80 to 90 per cent. of cases could be cured. When the treatment was followed in a sanatorium near the patient's home the chances of permanent cure were greater than if the patient went to the seaside. Several members expressed sympathy with the scheme, but some doubted whether the courts could afford another levy on the funds of their members. It was pointed out that similar schemes were being undertaken by county councils. The president replied that apart from what the county councils might do the friendly societies had enough consumptives amongst their own members to fill a sanatorium. He contended that it would be cheaper to cure a consumptive brother than to give him sick pay until he died and then to pay his funeral expenses. After a lengthy discussion a committee was appointed to confer with the representatives of other societies and to call a large meeting to consider the scheme further.

Medical Institute.

The annual report of this institution, which has recently been circulated, shows that the membership has been increased by 16 during the past year, the total now reaching 219. The number of books added during the year was 168, the total number of volumes upon the shelves being now 13,493

Health of Aston Manor.

This large district has recently become a municipality and the report of the medical officer of health, Mr. F. H. May, is the first which has been submitted to the newly elected corporation. In the report the corporation is congratulated upon the good health of the district and its continued low death-rate. For the past year this was 14 8 per 1000 of the population, and this, although calculated for the first time on the gross deaths belonging to the borough, whether registered therein or not, was 1·2 below the average of the past ten years. Mr. May attributes this lessened death-rate in part to the low mortality from infantile diarrhœa, although he adds that the improved sanitary condition of the town has no doubt borne its share in reducing the mortality and particularly that arising from zymotic disease. The number of cases of scarlet fever notified exceeds that of the preceding year, a fact which is very disappointing considering that 65 per cent. of the known cases have been removed to hospital. There were 383 cases notified of which 19 died, as compared with 361 cases and 18 deaths during the preceding year. There was a diminution in the number of cases of diphtheria and of membranous croup. With respect to measles Mr. May states that 25 deaths were registered as occurring from this disease during the year, as compared with 24 in 1902 and 29 in 1901. All of these were in children under five years of age. He says that many cases of measles and some deaths could be avoided if parents took a more serious view of the disease. He alludes to the common mistake that all children must have measles sooner or later which exists, especially amongst the uneducated and poorer classes, and when a case occurs in their households, he says, they seem to disregard altogether the greater incidence of the fatality amongst those who contract it under five years of age, and often the other children of the house are deliberately exposed to infection. In his opinion, mothers would be better educated up to a sense of the danger and of their responsibilities in this respect by the visitations of a female health inspector to the homes of the poorer classes where measles is reported. The notification of chicken-pox has not been required in Aston and Mr. May gives the following reasons for adopting this policy: (*a*) Only a small number of cases of chicken-pox are medically attended and therefore only a small number would be reported. Some slight cases of mild modified small-pox are less likely to be seen by a medical man than severe cases of chicken-pox. (*b*) The Infectious Disease (Notification) Act is a dual one but it is practically impossible to secure notification by members of the general public even if prosecutions were undertaken to enforce it. (*c*) School attendance officers notify many cases of chicken-pox which are medically unattended and doubtful cases which are under the charge of a medical man are usually brought under the notice of the health department without any compulsion. (*d*) Supposing that anything like complete notification could be secured it would be of little use unless every case were visited for purposes of verification either by the medical officer of health or some expert. (*e*) Such action on the part of the medical officer of health in supervising and checking the diagnoses of his medical brethren in the homes of their private patients, either with a consultation or independently, might lead to friction and has no legal justification, since the Local Government Board has decided that it is no part of the duty of a medical officer of health to verify notifications received by him unless there is any suspicion of *mala fides*. Moreover, by following such a course the onus of diagnosis is placed on the medical officer of health and the sanitary authority assumes a responsibility which does not belong to it.

April 19th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Lancashire Inebriates.

THE first reformatory of the Lancashire Inebriates Board was opened by Sir John T. Hibbert on April 14th. The board, constituted in 1899, represents the Lancashire County Council and all the county boroughs in the county except Oldham and consists of 44 members. The reformatory is near Whalley and the estate contains 326 acres. The contract for the building was £73,418. It is arranged in separate blocks round a quadrangle, with 12 separate "homes," each accommodating ten persons, with single and separate bedrooms. Women only are to be received at present. There is sufficient room on the site for the addition of a men's reformatory as soon as it is considered advisable. The intention is to employ the inmates at farm work and gardening and so far as possible to make the reformatory self-supporting. How much the 44 women will be able to do in this way is not very clear. The longest period of detention for women committed by the county and county borough justices is three years and there are now over 100 Lancashire women of this class in various reformatories outside the county. The director and medical officer of the reformatory is Dr. F. A. Gill who was formerly deputy medical officer at the Manchester prison and afterwards at Liverpool, while more recently he held a similar position in the Government Inebriates' Reformatory at Aylesbury. Dr. J. M. Rhodes of Manchester, in proposing a vote of thanks to Sir John Hibbert, said that nothing could be done with a drunkard unless detained for at least a year and he could not be got hold of in the present state of the law till he was practically hopeless. He thought the law should be so altered that the authorities could confine drunkards before their cases became chronic. Sir John Hibbert said there were 4,500 000 people in the county and last year alone 38,901 cases of drunkenness had come under the notice of the police, and these included 229 cases eligible for treatment in reformatories. The board had built first for women because their case was more urgent than that of the men. He spoke of the £160 000,000 spent annually in the United Kingdom on alcohol and said that "if rightly spent there would not be a poor man in the country." He hoped the reformatory would do something to reduce the evil that was eating into the vitals of our nation. Dr. R. W. Branthwaite, Home Office Inspector of Inebriate Homes, said that the first lot of cases received would be "practically irreformable." They had been drinking 15, 30, even 50 years, and were not to be reformed in three. But these cases must be "worked through" before the reformable ones were reached. "Because a case was not reformable they had no right to leave it about the streets" The simple facts brought forward at the meeting impress, and at the same time almost oppress, one with the magnitude of the evil done by alcohol, the misery it occasions, and the difficulty of preventing it so long as it is freely obtainable.

Are Town Dwellers Degenerating?

In a discussion rising out of a paper by Professor James Long descriptive of a colony of small holdings in Surrey, read to the Manchester Statistical Society on April 13th, Dr. J. Niven had something to say in favour of the town. He said that the statistics of this country for the last 50 years showed that "at the younger ages the death-rate had enormously improved and it was incredible to him that there had not been also an enormous improvement in physique," and that as so many crowded into the towns it was impossible to disbelieve that improvement was going on in the town population. Against the fresh air and sunshine of the country he set the high wages of the townsman, which enabled him to get wholesome and cheap food to an extent country people could not do. He had also a better house and better clothes. Some of these propositions will not be accepted unconditionally.

Bad Fish for Good Friday.

Although some people are said to prefer cod when it shines in the dark the majority believe that fresh fish is more wholesome and a pleasanter food than when it is stale. But some members of the Manchester city council seem to have doubts on the matter, for at the meeting on April 13th there was a long discussion as to whether or not one of the wholesale dealers in the fish market should be prosecuted for having offered for sale on Good Friday 371 pounds of unsound fish. A subcommittee had decided to prosecute but the markets committee reversed this decision, allowing the delinquent to apologise and to be the recipient of a "severe reprimand." The dealer explained that it was the fault of one of his men who opened a box of unsound fish and offered it for sale unknown to him. Slink meat and bad fish are known in most large towns and it is important that the municipal authorities should do all that can be done to protect the poor—for it is by the poor that such food is consumed—and not be diverted from their purpose by such letters as that in which the market tenant assured the committee that the offer of 371 pounds of bad fish "was a matter that had escaped his notice." In the end the council instructed the markets committee to institute a prosecution which most people will think was called for.

Cooperative Convalescent Homes.

The Coöperative Association, formed a few months ago to establish convalescent homes at Lytham and Otley, has now been registered under the Industrial and Provident Societies Act. At present 135 societies, members of the association, have subscribed for shares to the amount of £8640. To carry out the scheme £24,000 will be required and when the societies in the section have raised £16 000 the Coöperative Wholesale Society will take up shares to the value of £8000. This is a case of self help for which we may hope success.

April 19th

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Professor Andrew Peebles Aitken.

Dr. Andrew Peebles Aitken, who has for nearly 30 years [illegible]ology in the Royal [illegible]ied on April 17th at [illegible] received his educa- [illegible]here he graduated as [illegible]science in the department of chemistry in 1873 He subsequently worked at Heidelberg and on his return to Edinburgh he was appointed assistant to Dr. A. Crum Brown, the professor of chemistry in the University.

Public Health Appointment.

Mr. James McR. Cowie, M.D. Aberd., D.P.H., has been appointed medical officer of health and public analyst for Burton-on-Trent. Dr. Cowie has for some time been assisting Dr. J. Niven, medical officer of health of Manchester.

Aberdeen Dispensary: Appointment of Medical Officer.

At a meeting of the managers held in the town hall, Aberdeen, on April 15th the chairman, Lord Provost Walker, proposed the following motion which was agreed to unanimously:—

> That the managers resolve to enter in the minutes an expression of their deep regret at the early death of Dr. W. Findlay who had been for several years one of the medical officers of the General Dispensary and who had during the whole of the period conducted with marked ability the work falling to him in affording advice to the poor of the district and in imparting instruction to the medical students attending the practice of the institution.

The applicants for the post vacated by Dr. Findlay were Dr. J. W. Adam, Dr. W. F. Croll, Dr. Henry Fraser, and Dr. Anne Mercer Watson. The voting was by ballot. The first vote resulted as follows: Dr. Adam, 33; Dr. Croll, 28; Dr. Watson, 7; and Dr. Fraser, 6. The final vote resulted in the appointment of Dr. Adam, he having 38 votes to 35 given for Dr. Croll.

Public Health of Aberdeen.

A meeting of the public health committee of the Aberdeen town council was held on April 13th. It was reported that the death-rate for last month was 20·93 which is rather higher than for the corresponding month last year but somewhat below the average. Three cases of small-pox were reported, including one recent case of a woman in Palmerston-road.

University of Aberdeen General Council.

The statutory half-yearly general meeting of this council was held at Marischal College on April 13th, Principal Lang presiding. The report as to the statistics and finances of the University was submitted. The Principal said they would see that their position as a University was much more encouraging than it was a few years ago. For the first time for long he thought the University felt in the condition of being somewhat easy, not crippled and burdened with financial outlooks. Not that they should lay any flattering unction to their souls and think that all was right, but they were in a better position certainly than they were and they could hope to be in a better position still.

April 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The New Provost of Trinity College.

Dr. A. Traill, the recently appointed Provost of Trinity College, was entertained by the Corinthian Club on April 16th, Sir Charles A. Cameron, the President, occupying the chair. In reply to a remark of the President, Dr. Traill said that he was the first graduate of the medical profession who had been made Provost.

Royal Academy of Medicine in Ireland.

Dr. James Craig and Dr. R. Travers Smith are candidates for the office of general secretary to the Royal Academy of Medicine in Ireland about to be rendered vacant by the resignation of Mr. J. B. Story.

Chair of Botany in Trinity College.

At a meeting of the board of Trinity College held on April 16th Dr. Henry Horace Dixon was appointed to the chair of botany vacant by the resignation of Dr. E. Perceval Wright. Professor Dixon, who has been Dr. Wright's assistant since 1892, is the author of many important papers which have appeared in the Transactions of the Royal Society, the Royal Dublin Society, and the Royal Irish Academy.

The Registration of Nurses.

A meeting of the Irish Nursing Association was held at the Royal College of Physicians of Ireland on April 15th. Dr. James Little occupied the chair and in introducing Mrs. Bedford Fenwick said that he had an open mind on the questions which were to be brought before the meeting. The questions which had been raised in the discussion on the State registration of nurses as put forward had raised a storm which he had not any idea of until he received by post some documents bearing on the subject. Mrs. Bedford Fenwick addressed the meeting which was large, the hall being filled to its utmost capacity. In her statement she alluded to the fact that there were now 60,000 trained nurses in England and 6000 in this country; that registration of nurses was no novel question as it had been advocated for more than 30 years. A Bill, moreover, was now introduced which proposed that there should be a central executive body of 31 to control the registration of nurses in the three countries, the duties of which body had not been too closely defined, as what was desired was that a Bill should be brought forward which could be discussed in committee by those qualified to do so. Sir John W. Moore said that, like the chairman, he had an open mind on the subject, with a leaning towards registration. The motions which he proposed were:—

> 1. That it is essential the nurses throughout the United Kingdom should be efficiently educated for the performance of the responsible duties intrusted to them. 2. That a minimum standard of education and common rules of discipline can be secured only by an Act of Parliament. 3. That as a preliminary to such legislation it is desirable a Select Committee of the House of Commons should be appointed at an early date to inquire into the whole nursing question.

He went on to say that the British Medical Association had given its opinion in favour of registration many years ago but that a sudden opposition had sprung up in London to the proposal for the State registration of nurses. The proposal that a committee of the House of Commons should be asked to consider this question was certainly a reasonable one. He did not think it was wise on the part of the nurses to describe their calling as a "profession"; it would be much better to use the designation "calling." Dr. O'Carroll, in seconding the motions, remarked that at present there was nothing to prevent anyone being employed as a nurse who put on a uniform. Dr. A. R. Parsons said that there was no demand either by the nurses themselves or by the public for any State recognition of nurses. Sir Thomas Myles, on the other hand, could not understand why there should be any opposition to the proposed reform. Sir Christopher J. Nixon considered that the proposal was one which deserved to be supported by the Dublin medical schools. The motions were carried by a substantial majority.

The Belfast Board of Guardians.

A question of the payment of a medical fee came before the Belfast guardians on April 12th which illustrates the way in which Irish dispensary medical officers are treated. Dr. W. D. Donnan, dispensary medical officer of Holywood, near Belfast, wrote to the board stating that he had felt it to be his duty on April 9th to call in Dr. Gardner Robb, physician to the workhouse fever hospital, to see a dispensary patient who had a suspicious rash which he feared might be small-pox and whom he did not wish to send to the union fever hospital without having Dr. Robb's opinion. Fortunately, Dr. Robb did not consider the case to be one of small-pox and he begged to ask the board to sanction the payment of Dr. Robb's fee which was two guineas. The board declined to do so and one guardian, I regret to say a woman, said, "Let Dr. Donnan give Dr. Robb the two guineas himself," while the chairman added, "Yes, let him pay the fee himself. It is a great piece of audacity." The ground which the guardians take is that the city corporation receives small-pox cases into the Purdysburn Hospital and that they have nothing to do with such cases but they are clearly in error as such a contention could only apply to Belfast cases, while this was a *bonâ-fide* dispensary patient outside the area of the Belfast city corporation but within the Poor-law district over which the Belfast guardians have control, and Dr. Donnan was perfectly within his rights in asking for an expert opinion in what was undoubtedly a "difficult" case and a state of affairs provided for by the Local Government Board. Suppose the case had turned out to be small-pox and that Dr. Donnan had not been extra careful and that an epidemic of small-pox had as a result arisen, I wonder, then, what would this same board of guardians have said. Unquestionably it would have censured Dr. Donnan. The Belfast board of guardians must make provision for dealing with small-pox cases in its area which is outside the boundaries of the city of Belfast.

The Mater Infirmorum Hospital, Belfast.

From the twentieth report, just published, for the year ending Oct. 31st, 1903, it appears there were 1508 intern cases (932 medical and 576 surgical). 328 surgical operations were performed. 42 deaths occurred during the year, of which 32 were medical and ten were surgical cases. Of these seven were moribund on admission. The mortality was 3·5 per cent. There were 19,980 extern cases. The expenditure for the year was £5008 9*s*. 3*d*. The income was barely sufficient to meet current expenses and a special appeal is made for additional funds which are urgently needed.

Portrush Cottage Hospital.

The Hopefield Cottage Hospital, Portrush, a much needed institution, will shortly be opened formally. The wards have for the past three months been occupied by patients and efforts are being made to raise additional funds on behalf of the hospital.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Number of the Tuberculous in the Paris Hospitals.

A MEDICAL journal has just carried through an inquiry into the number of tuberculous patients under treatment in the Paris hospitals. Of 4117 patients passed under review 1685 were tuberculous—namely, 1146 men and 539 females, or a proportion of 40 per cent. A similar inquiry had already been made by M. Mourier, formerly director of the Assistance Publique, who arrived at the result of 45 per cent These figures are important at the present time when it has been decided to reserve two or three of the Paris hospitals exclusively for the use of tuberculous patients.[1] As a matter of fact, the number of tuberculous persons in Paris is far greater than is indicated by the above figures. Even when the 2000 tuberculous patients who are to be treated in the hospitals are taken away f
easily be 2000 others to
whether the patients will
of death" where they ca
nature of their malady? In hospitals when the plan of reserving certain wards for tuberculous patients has been tried as soon as those suffering from phthisis saw that they were to be in company with their fellow sufferers they insisted on leaving.

The Therapeutic Uses of the Peroxides.

M. Gilbert recently read a paper before the Society of Biology on the Therapeutic Uses of the Peroxides and as a sequel to this paper M. Albert Robin read another before the Therapeutical Society giving his experiences of this drug which he has for some time past employed. The peroxides of calcium and of magnesium give up the whole of their oxygen when they come in contact with the gastric juice. If, however, they are given in a capsule of keratine so that they can pass into the bowel before being decomposed they have a powerful antiseptic action. Under their influence the conjugate potassium indoxyl sulphate present in the urine in cases of septic absorption rapidly diminishes. Peroxides diminish the fœtor of the stools and are the best means for overcoming diarrhœa due to a fermentative origin. On this account they may be made to serve as a diagnostic agent, for they have hardly any effect in diarrhœa due to serous, vaso-motor, bilious, nervous, or tuberculous causes. M. Robin quoted two typical cases which were under his care at the Beaujon Hospital. One was that of a patient in the third stage of phthisis who had profuse diarrhœa, probably of tuberculous origin. The stools were liquid, without marked fœtor, very slightly coloured, and neutral or alkaline in reaction. Peroxide of magnesium in doses of one and a half grammes per diem had no effect and reliance had to be placed upon astringents such as tannin, opium, and bismuth. If these were given up the diarrhœa returned and oxide of zinc had to be given. The other case was that of a patient suffering from pleurisy who during convalescence developed acute diarrhœa with very fœtid stools, giving a markedly acid reaction to litmus paper. This condition seemed to be due to gastric hyperacidity, the existence of which was confirmed by an analysis of the stomach contents and which in its turn was due to fermentation. Peroxide of magnesium was given at first in doses of one gramme per diem so as to act on the stomach contents and afterwards in a keratine capsule so that it might act directly on the intestinal contents. Within a few days the stools became less frequent and lost their fœtor. As, however, they remained acid the stomach contents at the end of a meal were saturated by a mixture of calcium carbonate and calcined magnesia, two days after which the stools became absolutely normal. In the belief that oxygen liberated from the peroxides would be absorbed by the blood Hatch, Havald, Monó, and Munstein have suggested that magnesium peroxide should be given in cases in which the direct action of oxygen seemed advisable. They recommend its use in certain cases of anæmia and in certain cases of joint disease.

April 19th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Midwives' Petition.

A QUESTION of practical importance is at present before
nton of Zürich. As the rules
the cantonal hospitals, both
ients as well as those which provide for the needs of the pauper population, are at present under consideration the midwives of the district have petitioned asking that the fees charged to the paying class of patients should be raised. They plead that the present charges at the obstetric clinic should be raised as the interests of both the ratepayers and the midwives are suffering severely in consequence of the system now in force. The number of women admitted at the obstetric clinic for the purpose of their confinement has been rapidly increasing from year to year; it has, in fact, more than doubled in ten years, for there were 1344 admissions in 1902 as compared with 540 in 1891. Thus nearly one-fourth of all the confinements of the town of Zürich, which has a population of 160,000, take place at the clinic and three-fourths are attended by the midwives and the medical practitioners. I must here mention that the great majority of all the normal confinements, perhaps over 90 per cent., are conducted by the midwives and medical aid is only summoned in cases of abnormal labour, this portion of the work is falling into the hands of the numerous medical specialists, male and female. I must also add that the midwives are well trained for their duties as they have to spend six months at the clinic in study in order to obtain a legal diploma. They also have to attend repetition courses at the hospital every three or four years as long as they continue in the profession. The ratepayers of the canton of Zürich are put to considerable expense owing to the fact that the middle-class patients are undercharged at the clinic where they get the best of advice and attendance for nominal fees. The daily cost at the clinic is 2*s.* 5*d.* per head; the average amount paid in is only 1*s.* 5*d.*, and the deficit to be covered amounted in 1891 to £1700 but has risen in 1902 to £5100 for the obstetric clinic alone. The midwives argue that if this arrangement extended only to paupers nobody would have reason to complain but the middle classes have begun to use, or rather to abuse, these charitable institutions to the detriment of the midwives who are under a legal obligation to attend normal pauper confinements for the meagre sum of 12*s.*, whereas the patients who could pay from £1 to £2 for a confinement make use of the hospital. At present persons declaring their incomes at £80 a year pay only 8*d.* a day when in the hospital; this sum should be increased to 1*s.* 3*d.* per day. Persons declaring their incomes at amounts up to £120 should pay 2*s* a day instead of 1*s* as at present. It must also be remembered that declared incomes are notoriously some 20 to 50 per cent. short of the real income, owing to the high rate of income tax—namely, 1*s* 6*d.* in the pound. It seems most necessary that the canton of Zurich, which is hampered by a deficit now amounting to £160,000, should do everything in its power to avoid useless deficits as in the above case. This petition has caused the scale of charges for admission to the cantonal clinics to be returned to the authorities for revision.

Zurich, April 12th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cattle Plague.

THIS disease, also called rinderpest or bovine typhus, has often been introduced into Egypt from Turkey or Syria, where it is endemic as in South Africa and India. One of the first duties of the newly formed sanitary department in 1884 was to combat it and matters were then impossibly difficult owing to the complete absence of veterinary surgeons and all literature on the subject. In fact, the Egyptian Government of that day was so averse to increasing the number of English officials that it actually sent back to England, without even interviewing him, the first civilian veterinary surgeon who was brought out here to work for it. Now matters are happily improved, a large staff of English veterinary surgeons inspect the country, and a flourishing college for native students stands in the grounds of the sanitary department. In England and many other European countries cattle diseases are dealt with by the Agricultural Board but as this is unhappily non-existent in Egypt all veterinary questions are under the control of the sanitary department, so ably presided over by Sir Horace Pinching. Cattle plague died a lingering death in 1886 and Egypt remained free from it till about a year ago, when it was re-imported from Syria. Attempts were made last summer to get serum from Constantinople but inaccurate instructions which accompanied the supply caused the death of the cattle experimented on and the serum treatment became extremely unpopular. Now there is a well-appointed serum institute in the Abbassiyeh desert, near Cairo, where 100 bulls are kept immunised against cattle plague. Each bull is bled every fortnight and gives seven litres of blood each time; these seven litres yield 65 per cent. of serum and a protective dose of serum is 30 cubic centimetres per 600 pounds of the weight of the animal. Roughly speaking, fully grown beasts weigh 1000 pounds and bulls are chosen because they are stronger than cows and yield more blood. In order to immunise a bull five cubic centimetres of virulent blood are injected subcutaneously over one shoulder and an appropriate dose of serum over the other shoulder, according to the animal's weight. This is practically the simultaneous method of Dr. G. Turner of South Africa, which has been adopted in this country after experimenting with other methods. After the double injection the bull, the normal temperature of which is from 101° to 102° F., has fever for from six to ten days, the temperature running up to 105°. When the febrile reaction has subsided the bull is injected subcutaneously at one sitting with four litres of virulent blood which produces a second attack of fever lasting about a week, the temperature again rising as high as 105°. After the second attack of fever is over and the bull has rested four or five days he is ready to be bled to furnish protective serum. In two months' time, after four bleedings, he is reinforced with another four litres of virulent blood when febrile reaction again takes place. After another two months he is again reinforced and this may be repeated until he becomes "salted"—i.e., incapable of becoming affected by the toxin and unable to yield antitoxin—when he can be safely sold to the butcher. One animal, however, has now been in constant use for seven months. Virulent blood is obtained by bleeding at the height of the fever on the sixth day, allowing three days for incubation and three days for the fever to rise. To obtain serum as soon as a bull is bled the blood is allowed to clot in tall cylinders and the expressed serum is then decanted and centrifugalised in Cairo so as to get rid of any blood corpuscles which may be present, after which 0·5 per cent of carbolic acid is added as a preservative. Every 100 litres of serum so prepared are standardised by testing against virulent blood in a number of fresh bulls. The serum is then packed in bottles containing 220 cubic centimetres each and despatched to the veterinary staff in the districts. The quantity now prepared is 4000 doses a month, which is much less than the actual requirements, but it is hoped that shortly, owing to the increased strength of the serum, about 10,000 doses a month will be sent out. There are two methods of using the serum in the villages: (1) to give a dose of serum to each animal of a suspected herd, thus conferring a passive immunity for a period of from three to five weeks (the great advantage of this temporary treatment is that the farmer at a busy time of the year can continue to work his cattle on the land for ploughing, &c); and (2) to "vaccinate" by inoculating once by the simultaneous method already mentioned and thereby secure immunity for years. This second method is dangerous in the country districts because, owing to want of care and imperfect knowledge on the part of the owners, from 10 to 25 per cent. of the animals die. The chief causes of this high mortality, which has brought some discredit on the serum treatment, are that the ignorant owners unless prevented continue to work the cattle in the fields and also expose them without protection to cold air at nights even when the poor beasts are in the midst of their febrile reaction. However, at the Serum Institute, where the bulls are treated with the care necessary for all sick animals, very few die. For instance, not one has succumbed out of the last 80 immunised, though a slight mortality did occur early in the experiments before it was understood that sick nursing was so all important. Every beast's rectal temperature is taken by chart three times a day; it is stabled by night in clean sheds made of wood and matting, it is exposed to the sun all day, and its food is carefully regulated, consisting chiefly of clover, beans, and chopped straw, while of course it does no work. The institute since June has been under the control of Dr. W. St. C. Symmers, the professor of pathology and bacteriology at the medical school, assisted by one Englishman, two native veterinary surgeons, and a number of servants. Professor Symmers is specially fitted for this work after his long apprenticeship in the preparation of diphtheria and other antitoxins in England. In addition to this institute he is also controlling work at the slaughter-house in Old Cairo where a large number of animals are tested and partially immunised and whence suitable bulls are after quarantine transferred to the Serum Institute. The advantage of this quarantine process is that the animals can be carefully tested and if found to be suffering from any other disease they can be discarded and so less risk is run of infecting the bulls at the institute. Quarantine is just now of the highest importance because other diseases are prevalent, such as Texas fever (pyrosomiasis or hæmoglobinuria), foot and mouth disease, and a but little understood complaint which is thought to be Rhodesian fever. It is this last disease at which Professor Koch is now working in South Africa and which is associated with a rod-shaped protozoon in the red blood corpuscles, reminding one of malaria in the human subject. Professor Koch has been invited here in May by the Egyptian Government to give us the benefit of his knowledge on cattle diseases. Previous experience in Egypt and other countries tends to show that rinderpest will temporarily die down during the hot summer months but will reappear in the autumn and the Serum Institute must therefore continue to work at high pressure. Buffaloes also contract rinderpest but do not seem to be so susceptible as other cattle. Some gazelles which have recently died at the Zoological Gardens here had symptoms and post-mortem appearances closely resembling those of cattle plague. One of the best features of the Serum Institute is that it is practically self-supporting; over £6000 have been expended but this sum has been repaid by cattle owners, though the serum is invariably given to those who cannot afford to buy it. H. H. the Khedive, who is a considerable owner of cattle, has visited the institute several times and has sent many of his cattle to be immunised. This may encourage some of the disbelievers who are fully persuaded when their herds are attacked by food and mouth disease and Rhodesian fever that the serum is responsible. Already about 150,000 head of cattle have died, representing, it is calculated, a loss to the country of nearly £2,000,000. Fortunately, about one-fourth of the survivors in Upper and Lower Egypt are already immune after recent attacks of cattle plague. Veterinary tropical knowledge is quite in its infancy and experts cannot yet differentiate between some of the diseases I have mentioned either by clinical symptoms or post-mortem signs. Dr. Bitter and Dr. Dreyer are working daily at blood films from the sick animals and may in the future be able to throw some light on the problems which are of fascinating perplexity.

---

[1] THE LANCET, April 16th, p. 1035

Cairo, April 10th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Quarantine.

THE necessity of federal quarantine regulations was alluded to in a former communication. Since then the Tasmanian health authorities have written to the Board of Health of Victoria urging the necessity of making further efforts to secure federal quarantine. The board replied "that the time had arrived when joint quarantine regulations for Australia should be framed." As is usually the case, the passengers quarantined at Melbourne on arriving from New Zealand, owing to the outbreak of small-pox there, have made protests. One complaint was, however, unusual—being a charge of favouritism owing to the use of undue "influence" by a very influential personage. Mr. J.

Thompson, a member of the Governor's Council of Madras, with his family and a nurse, was quarantined with the other passengers by the steamer *Victoria* from New Zealand and they were all almost immediately released as the result of telegrams which passed between Mr. Thompson and the "influential personage." Dr. D. A. Gresswell, the chairman of the Board of Public Health, denies that there was any favouritism and states that Mr. Thompson and his family were released because it was considered that they had complied with the regulations, having been vaccinated several times.

The Declining Birth-rate in New South Wales.

The appointment of a Royal Commission to inquire into the decline of the birth-rate and the mortality of infants in New South Wales was mentioned in THE LANCET of Oct. 17th, 1903, p. 1132, and the names of the members of the Commission were at the same time given, Dr. Charles K. Mackellar, M.L.C., being the president. The Commission held 40 meetings and took the evidence of 96 witnesses, of whom 26 were medical practitioners and eight were representatives of the various religious denominations. The report, which is published by the Government printer in Sydney as a Blue-book of 62 printed pages and 27 full-page or folded diagrams, is dated March 3rd, 1904, and is signed by the President and 11 of the other 12 Commissioners. It is an exhaustive document dealing with every phase of the subject. The commission finds that there has been a marked decline in the birth-rate in New South Wales since 1899. It points out the remarkable unanimity of opinion among medical men that deliberate prevention had become exceedingly common during recent years and that the means used to this end are both deleterious to the general health and frequently bring about pathological sterility. The evidence, the commission says, shows conclusively that the practice of prevention by artificial means is common in all classes of the community and has greatly increased during the last 15 years. The inducement of miscarriage, it is said, is alarmingly frequent and justifies it being regarded as a well-defined factor in the decrease of the birth-rate. The commission suggests amongst other things that with a view to counteracting the desire for prevention among women increased public hospital accommodation in the metropolitan and country districts should be established for parturient women, and especially for married women, and that a large number of women should be encouraged to train as obstetric nurses. In view of the growth of procuration of abortion and miscarriage it is considered advisable that a department of the State Government should be intrusted with licensing, supervision, inspection, and control of private hospitals, lying-in homes, and maternity homes (other than public hospitals) where pregnant women are received for treatment or care in relation to their pregnancy or for their confinement. The commission states that the Government of New South Wales should take steps to prohibit the sale, distribution, importation, manufacturing, advertising, or purchasing or receiving of goods, articles, contrivances, or other things designed to be used for the prevention of conception in women. With the view to strengthen the religious restraint the churches are invited to institute and to devise a general crusade of such an impressive character as would arouse a recognition of the immorality and selfishness of the practice of deliberately restricting the birth of children. The practices involved in the limitation of families were responsible for much physical suffering, for a deadening of the moral sensibility, and for a degradation of character among those who resorted to them. These effects must have an unwholesome influence on the general character of the people who moved in a social atmosphere so vitiated. Defective health, defective morals, and defective character were already manifesting themselves as warnings of a more marked deterioration likely to ensue. Mr. Teice, actuary and manager of the Australian Mutual Provident Society, has compiled some statistics on the subject. He finds that the decrease in the birth-rate has been about 30 per cent. in 21 years. During the census periods of 1881 and 1891 the proportion of married women at ages up to 34 years did not differ materially from those above that age. The figures for 1901 show that the married women of ages 35 years and upwards exceed those below the age of 35 years by 30·6 per cent. This change in the proportions has been coincident with the decline in the birth-rate and he attributes the decreased birth-rate to the fact that the proportion both of married men and married women at the ages at which generation is most active has largely decreased. The reasons for this, in his opinion, are (1) the increasing luxury of the time; (2) the increased independence and employment of women; and (3) the cessation of immigration.

Hospital Affairs.

The annual report of the Sydney Hospital stated that the subscriptions amounted to £55 more than last year. During the year 4657 in-patients and 16,877 out-patients had been treated and 2627 major operations had been performed. The work had been carried on smoothly and efficiently. The x-ray department had been reconstructed and a second outfit added. —The diphtheria branch of the Sydney Children's Hospital at the Glebe has been closed, except for very urgent cases, the Government having arranged to provide accommodation for 37 diphtheria cases at Little Bay. Patients received at the Glebe will be injected with antitoxin and then forwarded to Little Bay.—The Infectious Diseases Hospital, Melbourne, started seven years ago is not open for patients yet but something like finality seems near. A memorandum, prepared by a conference of municipal representatives, for the maintenance and control of the institution has been agreed upon. The hospital is to be vested in the municipalities as trustees. The cost of maintenance is to be contributed on the basis of the annual assessment of the municipalities with quarterly claims on the Government for its moiety of the amount expended. The trustees are to appoint the committee of management, the term of office being three years. There will be on the committee representatives of Melbourne, Fitzroy, Richmond, St. Kilda, North Melbourne, Brunswick, and Coburg. The cost of maintenance of all patients from districts other than those represented on the trust is to be charged for at rates fixed by the committee.—The medical staff at the Women's Hospital, Melbourne, has suggested the formation of an external midwifery department in connexion with the hospital and the committee has asked the staff to formulate a scheme.—A curious question in hospital management is raised by a decision of the Department of Public Health in New South Wales. A man was taken by the police to the Western Suburbs Cottage Hospital for admission. The medical officer who saw him refused to admit the patient as he was intoxicated and violent and the institution had no wardsman to control him. The police then took the patient to the lock-up and summoned a medical man to attend him. This practitioner said that the patient had concussion of the brain. The Health Department has decided to deduct from the Government subsidy to the Western Suburbs Hospital the expenses incurred by the police in obtaining treatment for the patient.—Mr. Charles MacLaurin, M.B Edin., has been re-elected honorary assistant surgeon to the Prince Alfred Hospital, Sydney.

Charge against a Medical Man.

At the February sittings of the Supreme Court, Warrnambool, Victoria, Mr. Edmund D. la Touche was acquitted on a charge of performing an illegal operation on a young woman.

March 10th.

Obituary.

SIR HENRY THOMPSON, BART., M.B. LOND., F.R.C.S. ENG.,

SURGEON EXTRAORDINARY TO H.M. THE KING OF THE BELGIANS; EMERITUS PROFESSOR OF SURGERY AT UNIVERSITY COLLEGE, LONDON; CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL, ETC.

WE regret to announce the death which occurred on Monday afternoon last of the veteran and distinguished surgeon, Sir Henry Thompson. Sir Henry Thompson was only ill for a few days and bore his burden of 84 years so lightly and with such full appreciation of life that the announcement of his death has come as something of a shock to the medical world.

He was born on August 6th, 1820, at Framlingham in Suffolk, in which small market town his father, Mr. Henry Thompson, had resided for many years. His mother was Susannah the eldest daughter of Samuel Medley, the artist. Having received his early education at a neighbouring grammar school he determined to apply himself to the study of medicine and became apprenticed to a local surgeon in accordance with the custom of those days.

Having studied and assisted in practice for two or three years he proceeded to University College, London. His student days at University College have been described with some accuracy by him in one of his novels and seem to have been devoted to the pursuit of his science. His was a thoroughly healthy mind and his habits both of life and thought from the beginning of his working career were such as to encourage in a remarkable degree the development of the true surgeon, robust, active, and, above all, resourceful. He loved work and even as a student was never so happy as when mastering some intricate detail of surgical anatomy.

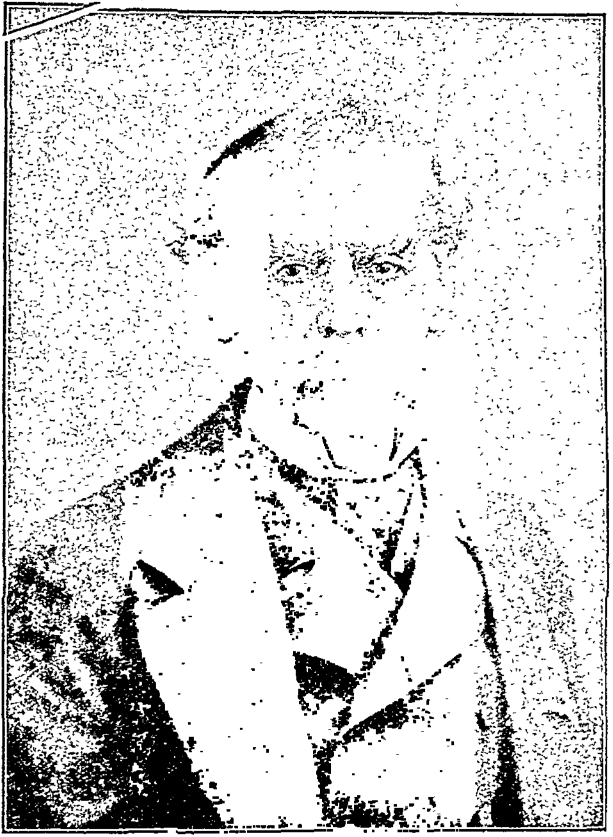
After an unusually successful career as a student Henry Thompson in 1850 took the diploma of Member of the Royal College of Surgeons of England, his great friend, the late Sir John Russell Reynolds, passing at the same examination, and a year later they both proceeded to the degree of M.B. at the University of London, Thompson securing the first place in obstetric medicine and the second place in surgery, and Reynolds the first place in medicine and the third place in surgery. His friendship with Russell Reynolds throughout the career of the latter, whose death we recorded in THE LANCET of June 6th, 1896, p. 1582, was unbroken and of the closest description. The mutual influence of these two leaders of our profession, the one upon the other, may be noticed in many steps of their respective careers and the following are Sir Henry Thompson's own words addressed to his old friend: "We first met among a crowd of freshmen, strangers, at the gate of University College, in the autumn of a year late among the forties. I know no other among the friendships then made which has so borne the test of time, none which has so soundly ripened, none which is now so highly prized as yours. You and I have watched with interest the other's course, divided as each has been between long periods of continuous devotion to professional study and short intervals of happy diversion in pursuit of art."

In 1850, on the retirement of Mr. Moncrieff Arnott from his post of surgeon to University College Hospital, Henry Thompson, who had served a portion of his term as house surgeon to that gentleman, was transferred in a similar capacity to his successor, the late Sir John Erichsen, and assisted the latter in his first operation as full surgeon. With Sir John Erichsen he maintained a warm and intimate friendship which continued until the death of the former in 1896. Thompson held more than one house appointment between 1850 and 1853, in which latter year he was appointed assistant surgeon to University College Hospital. This position he occupied for ten years and in 1863 became full surgeon. During this period he made a point of studying the methods of the great masters of other schools, for example, Civiale in Paris and Keith in Aberdeen. Three years later he became professor of clinical surgery in University College, of which body he had been for more than five years a Fellow. Throughout the most active portion of his career his old hospital and school received the benefit of his valuable work and during his connexion with the institution he was associated with a group of men whose names will ever be remembered in medicine. In addition to Reynolds and Erichsen, Sir Henry Thompson had as colleagues at different times Sharpey, the pre-eminent physiologist; Ellis, the anatomist; Richard Quain, the surgeon; Parkes and William Jenner, who need no qualification; Walshe, Wilson Fox, and Berkeley Hill. With these men he worked to raise the medical school of University College, London, to its very high level, and although his private practice was very extensive and successful it was not until 1874 that he retired from the active staff and became consulting surgeon.

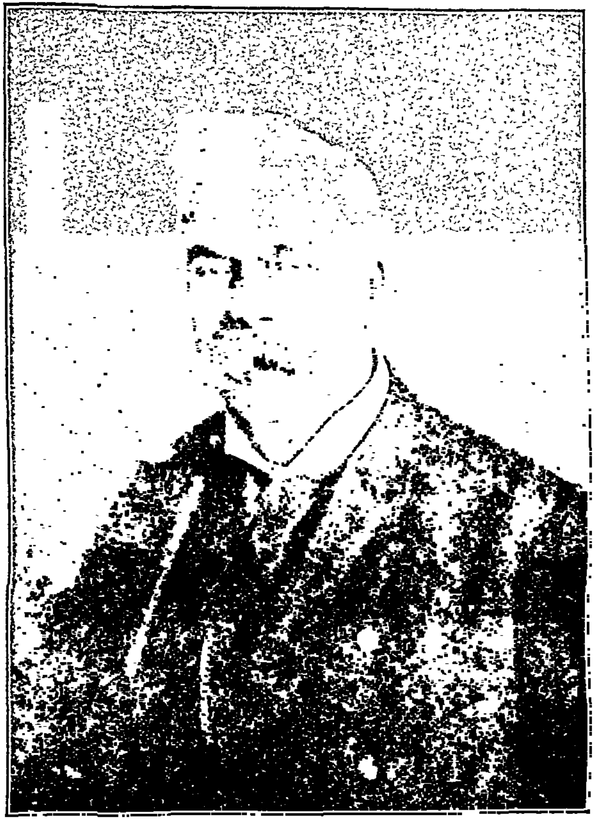
Sir Henry Thompson's connexion with the Royal College of Surgeons of England dates from 1850 when, as above mentioned, he became a Member of that body. In 1852 his masterly essay on Stricture of the Urethra gained him for the first time the Jacksonian prize; a year later he passed the examination for the Fellowship and in 1860 he again successfully competed for the Jacksonian prize, the subject being the Healthy and Morbid Anatomy of the Prostate Gland. He thus shares the honour with the late Mr. George Calvert of securing the prize on two occasions. This, when we call to mind that the prize was instituted in 1801 and that there is no regulation preventing several attempts to gain it, is a noteworthy achievement. In 1883 he was appointed Hunterian Professor of Surgery and Pathology at the Royal College of Surgeons of England in succession to Mr. Jonathan Hutchinson. While acting as assistant surgeon, and afterwards as surgeon, to University College Hospital Sir Henry Thompson performed a very large number of operations for stone with singular success and as this success likewise attended his operations in private practice his reputation from being local became virtually world-wide. Among his patients was the late King Leopold of Belgium, upon whom in 1863 he performed a most difficult and dangerous operation with perfect success. His Majesty had already been attended by the famous Civiale, under whom Thompson had studied, and a partially successful lithotrity had relieved his symptoms. They returned, however, with severity and when Thompson saw his patient in Brussels the King, sceptical of the value of surgery, refused to allow a proper examination to be made. Thompson, however, was firm as to the necessity, and persuaded the patient to trust him, with a completely happy result, the crushing of the stone being completed in three sittings. The King appointed him his surgeon-extraordinary and also made him a Companion of the Order of Leopold of Belgium, in which order he was promoted in 1876 to the grade of Knight. The present King of the Belgians also appointed him surgeon-extraordinary. Some ten years later Thompson, who in the interval had been made a Knight, was summoned to the bedside of the Emperor Napoleon III., then living in exile at Chislehurst. He diagnosed the presence of a vesical calculus and recognised the urgency of the symptoms, but the Emperor could not decide to have lithotrity performed until some months later. Too long a time had really elapsed and although the surgical proceedings were justified at the post-mortem examination, as being calculated to give the illustrious patient his only chance of life, he succumbed after the second sitting.

Sir Henry Thompson's special surgical experience enabled him to have very distinct views upon all the various methods of procedure in vesical cases, and his opinion was highly valued by medical men, because he was so clear in his explanations and so quick to suit treatment to circumstance. Throughout his career Sir Henry Thompson was a warm advocate of the suprapubic operation as opposed to the lateral, and for his advocacy he gave six reasons, viz.: (1) that in the suprapubic operation there is no important structure near the line of the incision that can be injured by the knife or forceps—the rectum and sexual organs being out of the way; (2) there is more space for removing the stone; (3) there is no risk of arterial hæmorrhage; (4) the incisions are more easily made in that they are made under the eye of the operator; (5) the outflow of urine is easy and direct; and (6) antiseptic dressings can be easily and readily applied. He had an unrivalled opportunity of verifying his views, for throughout five-and-twenty years he was engaged in operating on such cases with extremely successful results. His tact in the management of a patient was almost equal to his skill, while his mechanical ingenuity has been of great service to the profession and a large number of improvements were introduced by him in such instruments as are in common use in vesical and prostatic operations.

The literary works of Sir Henry Thompson were popular as well as practical, for the profession, students and practitioners alike, recognised in what he wrote his perfect mastery of his subject His principal work was "Diseases of the Urinary Organs," which was first published in 1868, and consisted of a series of lectures delivered by him at University College, which, having been reported verbatim by a shorthand writer, were printed with a few alterations and condensations in THE LANCET. The volume of 1868 was a somewhat meagre-looking work, but in its seven subsequent editions it has gradually increased in size until in 1888, when the eighth edition was published, it formed a substantial text-book. This edition contains a *résumé* of Sir Henry Thompson's entire experience in operations for calculus up to the end of 1885, numbering in all about 900 cases The general aim of the work was to produce in condensed form an epitome of practical knowledge on the subject of urinary diseases, culled not only from the author's experience but from the works of the leading British and foreign writers and operators. The book has been translated into French, German, Italian, Spanish, and Russian. His other and supplementary work, "Practical Lithotomy and Lithotrity" has perhaps achieved an even greater success than the foregoing, being used as a guide to successful operation throughout the medical schools of Europe. "Diseases of the Prostate," founded on his Jacksonian essay of 1860, has been through six



SIR HENRY THOMPSON, BART., F.R.C.S. ENG.



SIR PHILIP CRAMPTON SMYLY, F.R.C.S. IREL.

large editions, and "Stricture of the Urethra," based upon his former successful dissertation, has in a much enlarged and improved form been re-published three times. He contributed largely to the medical journals, to the Transactions of various learned societies, and to such compilations as "Holmes's System of Surgery," in which he supplied the section dealing with the Surgery of the Urinary Organs. Although his special subjects occupied the more active moments of his life Sir Henry Thompson took the widest interest in the topics of the day and was the author of a very large number of articles which appeared in various first-class magazines and reviews, dealing with such diverse subjects as Moderate Drinking, Cremation and the Disposal of the Dead, Diet in its Relation to Age and Activity, and a Serious Attempt to Estimate the True Value of Prayer for the Sick, the last named, in the form of a letter to the late Professor Tyndall, causing considerable stir in theological circles. His opinions on the subject of cremation were very decided and he may, in fact, be said to have been in great measure the moving spirit in the inauguration of the revival of that method of disposing of the dead. From 1874 onwards he was president of the Cremation Society and did much to forward its propaganda both in England and on the continent. On several occasions Sir Henry Thompson called public attention to the loose system prevalent in the matter of giving and receiving certificates of death. He was largely instrumental, by his letters to the medical and lay press, in drawing attention to the risks run by the public under existing methods, and when in 1892 Neil Cream, the poisoner, was condemned to death Sir Henry Thompson returned to the attack. By means of a deputation to the Home Secretary the matter was brought under the notice of the Government which ordered a Select Committee of Inquiry on Death Certification.

As a novelist Sir Henry Thompson—under the *nom de plume* of "Pen Oliver"—on two occasions made a more or less successful bid for popular favour. "Charlie Kingston's Aunt," if it does not rank high as fiction, undoubtedly shows imaginative gifts on the part of its author and is interesting in that it presents also a truthful picture of the life of a medical student some 50 years ago. His second work of fiction, "All But, a Chronicle of Laxenford Life," published in 1886, is a more ambitious work, and although its plot is commonplace it forms interesting reading. The earlier chapters comprise sketches of life in a Suffolk village and are full of humorous touches. Sir Henry Thompson was at his best when describing the quaint sayings and doings of the old-fashioned village folk among whom he had been born and bred, while in this book there is a fairly successful attempt at a psychological study—namely, the complex character of Lord Arthur Wynstanley. An additional charm is given to this novel by 20 full-page drawings by the author, in one of which he has portrayed himself as he appeared in 1885.

As an artist Sir Henry Thompson was much more successful than as a novelist. He had doubtless inherited his artistic talent from his grandfather, Samuel Medley, the painter of the well-known picture of a meeting of the Medical Society of London which hangs in the rooms of that society; while it must be remembered that he hailed from the county of Constable. From student days he had cultivated the habit of drawing what he saw, and after his appointment as surgeon to University College Hospital he painted regularly under the tuition of well-known academicians and was frequently "hung" at Burlington House.

As a host Sir Henry Thompson was famous for his "octaves," dinners of eight courses for eight people at eight o'clock. The company was always as carefully selected as the food, and during a quarter of a century the most famous figures in the contemporary worlds of art, letters, science, politics, diplomacy, and fashion found themselves sitting at his board.

Sir Henry Thompson, who was created a baronet in 1899, married in 1851 Kate Loder the famous pianist. Lady Thompson, who has been an invalid for years, survives her distinguished husband and her son, the present Sir Herbert Thompson, succeeds to the title. To them we tender our sympathies on the loss of the many-sided brilliant man who for so many years adorned the ranks of our profession. As man of letters and man of science, as man of work and man of pleasure, as artist and social reformer alike, Sir Henry Thompson has left his mark upon his generation.

The funeral took place on Thursday at the Golder's Hill Crematorium, the ceremony being brief and private, in accordance with Sir Henry Thompson's instructions.

SIR PHILIP CRAMPTON SMYLY, M.D. DUB., F.R C.S. IREL.,

HONORARY SURGEON TO THE KING.

ONE of the most prominent members of the medical profession in Ireland has been removed by the death of Sir Philip Smyly, a man endowed by nature with many gifts and worthily occupying a high position. His last illness was of only a few hours' duration but he was a chronic sufferer from gout and his intimate friends had for about two years been aware that his constitution was seriously undermined. He had recently been on a visit to England, from which he had returned to his residence in Merrion-square, Dublin, and was there attacked with symptoms of cerebral hæmorrhage which proved fatal on April 8th.

His father, Josiah Smyly, was a well-known Dublin surgeon whose two sons, Philip Crampton Smyly and William J. Smyly, have in different branches of practice conferred honour on the family name which is commemorated by the Smyly Ward for children in the Meath Hospital. Sir Philip Smyly was born in Ely-place, Dublin, in June, 1838. When his thoughts were turned towards the medical profession the apprenticeship system was still in operation and he was accordingly indentured to his grand uncle Sir Philip Crampton who was made a baronet in 1839 and was three times President of the Royal College of Surgeons in Ireland. Sir Philip Crampton died in 1858 and his pupil was then transferred to Professor W. H. Porter. Young Smyly also attended classes at Trinity College, Dublin, and at the school of the Royal College of Surgeons in Ireland and acquired a knowledge of clinical work in the wards of the Meath Hospital. His student career gave some premonition of his future distinction from the importance of the prizes which were awarded him. In 1860 he became qualified as M.B. Dub. and L R C P. Irel., after which he studied surgery and ophthalmology in Berlin and Vienna under Langenbeck, von Graefe, and other notable professors. In 1861 he was admitted L.R C.S Irel. and was appointed surgeon to the Meath Hospital as the successor to his former teacher, Professor Porter, an appointment which he continued to fill for more than 40 years. In 1863 he graduated as M.D and was admitted F.R.C S. Irel. In 1878, at the age of 40 years, he had the exceptional fortune to be elected President of the Royal College of Surgeons in Ireland and from 1893 to 1900 he represented the College in the General Medical Council. From 1869 to 1895 he held the appointment of surgeon-in-ordinary to successive Lords Lieutenant of Ireland. In 1892 he was honoured with a knighthood. In 1895 he was made surgeon-in ordinary in Ireland to Queen Victoria and in 1901 honorary surgeon in Ireland to King Edward VII., a position which he retained to the end of his life. In 1897 the Household medal was conferred on him and in 1902 he received the Coronation medal. Other appointments which he held were those of president of the Irish Medical Association, president of the Irish Schools' and Medical Graduates' Association in London, consulting surgeon to the National Children's Hospital in Harcourt street, consulting surgeon to the Rotunda Hospital, and vice-president of the Royal Zoological Society of Ireland.

Sir Philip Smyly's practice was naturally both extensive and lucrative. He was at the same time noted for his kindliness of disposition, his generosity to deserving causes and charitable objects, and his sympathetic manner towards his patients of all classes. For many years before the appearance of specialists in Dublin he was looked upon as the foremost expert in Ireland on affections of the mouth and throat. So long ago as 1862 he published a paper on the Surgery of Cleft Palate, introducing some specially curved knives suitable for staphylorrhaphy. In the *Dublin Journal*, 1883, he described a variety of mirrors for demonstrating the larynx. Besides being surgeon to the Throat and Ear Hospital for many years he filled the office of president of the British Laryngological Association for 1889–90. In connexion with general surgery he associated himself with his late colleagues at the Meath Hospital, the eminent surgeons Professor Porter and Dr. Macnamara, in advocating ligation of the common femoral—known as Porter's operation—for the treatment of aneurysm of the femoral artery.

In personal appearance Sir Philip Smyly possessed the advantages of good looks and must be described as a man of fine presence. He was also a good conversationalist and possessed a variety of agreeable accomplishments, one of which was a proficiency in playing the violin. He had a high position in the Masonic Order, being a member of the Supreme Council of the thirty-third degree for Ireland; of which body he was the Grand Chancellor. He was also the representative of the Supreme Council of England. In 1864 he married the Honourable Nina Plunket, daughter of the third Baron Plunket and sister of the late Archbishop of Dublin. Three sons and five daughters were born to them, one of the sons being the present Chief Justice of Sierra Leone.

His funeral, which took place at Mount Jerome Cemetery, was attended by a great concourse of mourning friends and sympathetic spectators. On the arrival of the procession at the cemetery the draped mace of the Royal College of Surgeons in Ireland was placed on the coffin, the College being officially represented by Sir Lambert H. Ormsby, the President.

Medical News.

University of Edinburgh.—The following is the official list of passes at the recent professional examinations for degrees in Medicine and Surgery:—

First Professional Examination.—G. J. Adams, R. C. Alexander, A. C. Barker, William Beggs, J. A. Belcham, Henry Blyth, William Boyd, Alexander Bremner, F. V. Nanko Bruce, Henry Burns, P. D. Cameron, Peter Chalmers, George Coats, C. E. A. Coldicut, H. M Cook, A. C. Court, John Crocket, F. J. Davidson, C. H. Derksen, J. A. Duggan, W G. Evans, J. P. Falvey, John Findlay, William Fleming, Kenneth Fraser, K. N. Ghosh, A. B. Gordon, Peter Gorrie (with distinction), A. G. M. Grant, R. D. Latimer Greene, J. O. Hamilton, R. W. Hauman, F. W. Hay (with distinction), W. S. Heron, A. M. Hewat, St. G. M. L. Homan, J. J. Jervis, M. J. Johnston, C. W. Kay, A. W. Kendall, H. W. Kerrigan, A. F. Lee, A. R. Leggate, Cecil R. Lethem, C. L. Louw, H. B. Low, G. J. Luyt, B.A., David M'Carroll, L. G. M'Cune, W. S. M'Cune, John Macdiarmid, John V. MacDonald, Thomas MacEwen, A. E. M'Iver, G. M. Mackay, W. J. M'Keand, J. C. Mackenzie, E. R. D. Maconochie, Edward P. Maitland, Norman Martin, W. J. Mayne, R. C. J. Meyer, B.A., J. E. Mitchell, T. S. Mitchell, J. A. Morris, G. S. Norman, J. H. H. Pearson, A. A. W. Petrie, J. P. du Plessis, N. H. Prior, E. M. Reid, J. J. van Rensburg, Philip Roytowski, M. W. Ruthven, P. H. Salmond, Charlotte D. Schaeffer, Frederick Shannon, R. G. Sherlock, John T. Simson, J. D. Skinner, E. Drybrough Smith, W. B. Somers (with distinction), H. M Spoor (with distinction), W. A. Stewart, J. Wightman Stirling, William Stobie, Adam Tait, J. C. Tennant, Eleanor M. Thompson, A. E. Turnbull, H. S. Wallace, F. K. te Water, and Adam White.

Second Professional Examination.—J H. Aikman, M.A., J. A. Ainscow, A. W. Atkinson, R. C. E. Atkinson, R. G. A. Bagnall, C. F. Bainbridge, C. R. M. Baker, D. M. Barcroft, A. J. Beattie, E. H. Black, Richard Bladworth, F. H. Bradley, I. W. Brebner, Mary Brown, T. Graham Brown, B.Sc., D. S Buist, C. H. Burgess, S. T. Champtaloup (with distinction), A. E. Chisholm, J M. Christie, W. I. M. Clark, R. D. Clayton, William Core, M A., S. G. Corner, Denis Cotterill, Willi Cramer, Ph.D., R. G Cunningham, Jagonmohon Dass, Arnold Davies, A. M'D. Dick (with distinction), J. T. Dickson, T. H. Dickson, M G. Gill, A. M. Drennan (with distinction) Robert Duncan, James Dundas, D. D. Dunn, E. W. Dyer, S. S. Dykes (with distinction) David Eakin, J. G. Fleming, M. S. Fraser, Robert Fraser, J. W. Frew (with distinction), W. J. Geale, Laurence Gibson E. C. Girling, G. A. Gordon, W. L Gordon, W. H. Gowans, K K. Grieve, James Grimoldby, George Gunn, J. A. Harley, G. H. Howe, F. O. Inglis, Blanche M. L. Johnston, T. B. Johnston (with distinction), N W. Kidston, A. G. K. Ledger (with distinction), Alfred Leitch, Olive T Leonard, Peter Lornie, J. P. Lowson, R. D. M'Allister, J. S. Macdonald, W. K. Macdonald, J. W. S. Macfie, W. O. S. M'Gowan, G. B. Macgregor, T. S. M'Intosh D. F. Mackenzie, J. N Maclaughlin, Murdo Maclean M.A, John A. MacLeod, Helen M. M'Millan, John B. M'Morland, Robert P. M'Morland, A. C. B. M'Murtrie, Kenneth M Murtrie, J. M. Macphail, J. N. M Turk, David Mann, J. S. Manson (with distinction), Jamesina J Marr, R. P. Mathers, John Mathewson, M.A, G. M. Melville, C. Irvine Milne, C. James Milne, H. J. More, R. H. Nolan, J. S. Orwin, J. S. Peebles, A. M'Tier Pirrie, B Sc, George Pollock (with distinction), H. B. Porteous, Austin Priestman, C. A. Purnell, Claude Pycroft (with distinction), Mabel L. Ramsay, Gustav Raubenheimer, W. H. Riddell, C S. U. Rippon, John Ritchie (with distinction), H D. Robb, R. M N. Robb, W. S. I. Robertson, Æneas Rose, M A., Frank Ross, J M Donald Ross, Z M. H. Ross, Eustace Russell, James Scott, T. H. Scott, A. D. Stewart (with distinction), H. G. Sutherland, W. J. Taggart, K. R. Tampi, D. R Taylor, H. V. Taylor, William A. Taylor, C. H. Tewsley, E. R. Thompson, H. H. Thorburn, J N. Turnbull, Annie D. Urquhart, A G. Visser G. F. C. Wallis Thomas Walsh R H. Walton, A. I. Shepheard Walwyn, Richard Wilkins, C. H. Williams, W. E. R Williams C. R. Wills, Ethel Wiseman, R. M. Wishart, A. F. Wright, Emily C. Wybourne, and A. W. Young.

Old Regulations.—George A. Grierson.

Third Professional Examination.—Thomas Addis, Francis Aitken, D. C. Alexander, J. C. D. Allan, A. C. Alport, A. G. Anderson, William Anderson, G. S Banks, D. M'F. Barker, J. M Barkley, W. J. E. Bell, C. E Blair, D. P. Blair, George Blair, R. A. Blake, Herbert Brown, J. W. Cairns, T. F. Campbell, H. M. Cargin, Marjorie Duake Cohen, H. P. Cook, James Craw, D. C. Crole, J. A. Cruickshank, A. B. Darling, Thomas Davidson, M.A., J M. Dickson, H. A. Edwards, C. E. Elliston, F. E. Field, C. N. Finn, N. C Forsyth, R. S. Trew, W. G. Fröhlich, Jessie H. Gellatly, William Gemmill, Eleanor A. Gorrie, J. M. Grant, Joseph Green, C. Rose Greenfield (with distinction), J C. Grieve, James A. Gunn, M.A, B Sc., George Hadden, J. D. Harmer, Ada A. Hatchard, A. S. Hendrie, W. M. Hewetson, Jean S. Hogg, J. R. Holgate, Joseph Ings, T. Scoresby Jackson, J. P. S. Jamieson, J. H. H. Joubert, G. P. Joy, M.A., Solomon Kark, Ethel Landon, J. M Lauder, James Lindsay, W. L. Locke, John MacDonald, Peter M'Ewan, M A. (with distinction), T. A. MacGibbon, J. D. M'Kelvie, K. W. Mackenzie, Murdo Mackinnon, A. C. M'Master, Stewart M'Naughton, Charles M'Neil, M.A., N. N G. C. M'Vean, S. E Martin, E S. Massiah, Alexander Mathieson, D. M. Mathieson, M.A., A. I. Miller, C. M. Mirylees, C. E S. Mitchell, J. S Mitchell, H. B. Morris, D. L. Morrison, R. R. Murray, A. W. Neill, G. P. Norman, A. J. R. O'Brien, A. A. Ollivierre, D. H. Paul, H. E. Rawlence, Charles Reece, A. E. Carey Rees, B.A [illegible] M A., W. [illegible] Alexander [illegible] Selkirk, [illegible] tinction), S. A. Smith, T. R. Smith, A. G. V. van Someren, A. B. Spence, J. R. Tannahill, J. A. R. Thompson, R. B. Thomson, Nettie B. Turnbull, Edward Valenzia, A N. J. Vizarat, Frances M. Wakefield, R. C Walker, H. E. A. Washbourn, H. C. Weber, J. D. Wells, W. H. Welsh, F. P. Wernicke, Elsie B. Wilkie, H. C. Wilson, and James Young.

London School of Tropical Medicine.—Of the students of the above school who presented themselves for the examination at the end of January-April session, 1904, the following have passed:—

Norah Lenwood,* A. L. Hoops,* W. M. Eaton,* J. B. Cleland,* Olive McDougall,* K. McGahey,* J. Eldon, J. E. M. Brown, M. E. Leicester, A. E. E. Twynam, R. L. Roe, H. G. McKinney, G. F. Whyte, C. T. Costello, and C. W. Somerville.

* Passed with distinction.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.—The following candidates have passed the first professional examination:—

A. Honours.—James Murray and E. Waide.

B. Pass.—P. H. Black, S Blake, A. Curry, E. Evans, H. S. Johnston, G. S Levis, F. Mahony, A. E. S. Martin, Richard Power, G. W. Stanley, and J. P. Zeederberg.

Completed the Examination.—W. Breen, R. J. Brookes, P. Ferguson, J. P Grainger, C. A. O'Burne Ryan, G. G. Stephenson, and P. J. Williams.
